## FACTORS FOR CONVERTING ENGLISH UNITS TO METRIC UNITS

The following factors can be used to convert English units in this report to the International System of Units (SI).

<u>Multiply English units</u>	<u>By</u>	<u>To obtain SI units</u>
acre	0.4047	square hectometer ( $\text{hm}^2$ )
acre-ft (ac-ft)	1233	cubic meter ( $\text{m}^3$ )
cubic foot per second ( $\text{ft}^3/\text{s}$ )	28.32	liter per second (L/s)
foot (ft)	.3048	meter (m)
gallon per minute (gal/min)	.06309	liter per second (L/s)
mile (mi)	1.609	kilometer (km)
temperature, degrees Celsius ( $^\circ\text{C}$ )	= 0.556 ( $^\circ\text{F}-32$ )	

## SELECTED DATA FROM THERMAL-SPRING AREAS, SOUTHWESTERN MONTANA

By

Robert B. Leonard, Tordis M. Brosten, and Norman A. Midtlyng

### INTRODUCTION

During 1975-77 the Montana district of the U.S. Geological Survey collected and assembled data describing the flow, temperature, and chemical characteristics of thermal and related waters. The work was part of an assessment of the geothermal resources of southwestern Montana, excluding Yellowstone Park. The purpose of this report is to present representative data from 24 thermal springs and 3 deep wells where water temperatures exceed 38°C (100°F).

Initially, the data base included references reported by Waring (1965). The data base also included unpublished chemical analyses of water samples and related data collected during 1959-73 by the Montana State Board of Health (now Montana Department of Health and Environmental Sciences), the Montana Bureau of Mines and Geology, and by graduate students for theses. Results of analyses and engineering reports were collected from landowners, and additional published and unpublished data were collected by Geological Survey investigators during 1967-75 (see Selected references).

Tabulation of the data revealed wide discrepancies in reported parameters for some sites. Inadequate description of the sampling sites limited the value of much of the previously reported data, because most of the thermal springs were characterized by multiple outlets. The rate, temperature, and chemical composition of flow at the various outlets commonly differs and may fluctuate seasonally as a result of dilution by shallow ground water. Therefore, most of the sites were revisited to obtain information needed to expand, evaluate, and fill omissions in the data base. Special effort was made to augment data collected during the summer of 1974 at 21 hot springs by other Geological Survey investigators with similar data collected during other seasons.

Field measurements of rate, specific conductance, pH, and temperature of flow at the various outlets, particularly those having the highest temperatures, were compared with previously reported determinations. At some sites partial analyses for chloride or other relatively stable constituents sufficed to confirm similarities or dissimilarities with previously sampled waters. At other sites, more detailed analyses were needed to describe a source initially or to replace dissimilar, and possibly erroneous, information in the preliminary listing. Where correlation

was established, new data were merged with existing data according to location. Samples of associated cool waters were collected to evaluate the possibility that they compose part of the thermal effluent. Some questionable existing data were retained because they were the sole source of information that may describe long-term fluctuations in the chemical and physical properties of the thermal waters.

Chemical analyses and associated data are grouped in tables 1-27 by hot-spring areas, arranged in downstream order according to major river basins, and indexed numerically in figure 1. Locations of individual sites within each area are described by name and by a station number composed of latitude and longitude. Names formerly used to identify the hot springs are shown in parentheses.

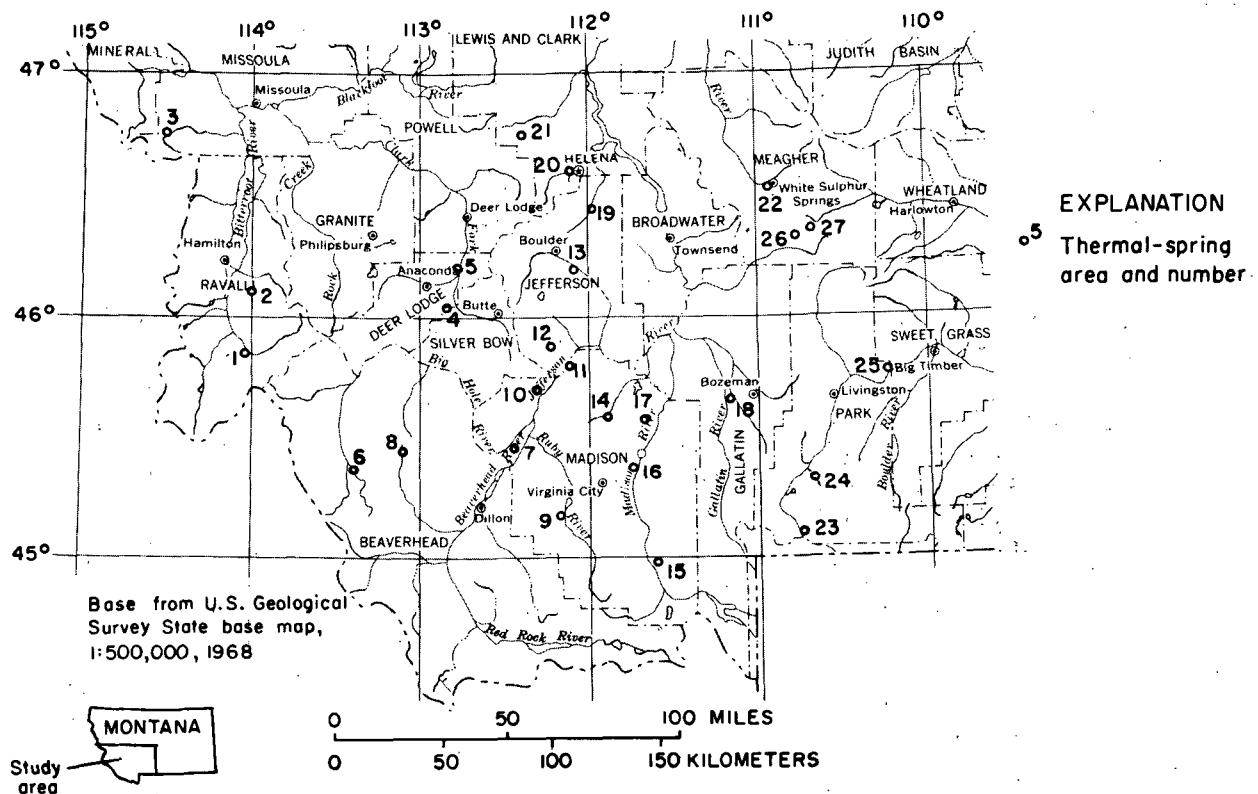

Figure 1.--Location of study area.

Reported rates of flow, particularly at commercially developed springs, vary widely according to the observer or use of the water. A large part of the flow normally occurs as seepage. Where feasible for this study, flow was measured directly using the Hoff or Pygmy current meter, a Parshall flume, or a container of known volume and a stopwatch.

Many apparent discrepancies in data collected in the past at a given site are attributable to different sampling, analytical, or reporting techniques. For example, pH values normally were determined in the field by USGS and in the laboratory by other investigators. Changes in the pH and the concentrations of bicarbonate and calcium commonly accompany cooling and prolonged storage of untreated thermal waters before analysis. The concentrations of dissolved solids for samples collected by USGS are the calculated sum of constituents; although roughly comparable some of the earlier determinations are of the residue on evaporation. Most of the chemical analyses in this report are of samples collected after 1973 by Geological Survey personnel according to techniques outlined by Presser and Barnes (1974) and analyzed by the Survey either in the National Water Quality Laboratory in Denver, Colo., or in research laboratories in Menlo Park, Calif.

All the included data describing composition of gases, stable isotopes, radioactivity, and subsurface temperatures were collected by the U.S. Geological Survey during 1974-77 (tables 28-31). Analysis of samples collected during the current investigation for determination of the composition of gases associated with the thermal waters (table 28) and for their content of the stable isotopes, oxygen-18 ( $^{18}\text{O}$ ) and deuterium (D) (table 29), was expedited by Mariner to ensure comparability with the results of his previous investigation (Mariner and others, 1976).

The isotopic data are expressed in the delta ( $\delta$ ) notation:

$$\delta_x = \frac{R_x - R_{\text{std}}}{R_{\text{std}}} \times 10^3$$

where

$R_x$  = reporting unit in parts per thousand,

$R_x$  = ratio of isotopic concentration of the sample (D/H or  $^{18}\text{O}/^{16}\text{O}$ ), and

$R_{\text{std}}$  = ratio of isotopic concentration of the standard (Standard Mean Ocean Water, or SMOW, in this report).

Most of the major hot springs and some associated cooler waters were sampled by the Geological Survey for determination of gross alpha and gross beta activity by the Montana Department of Health and Environmental Sciences. Results of the analyses (Larry Lloyd, written commun., 1976, 1977) are included in table 30. Additional samples for determination of dissolved uranium, radium-226, and radon by the National Water Quality Laboratory were collected mainly at sites where the Montana Department

of Health and Environmental Sciences analyses revealed abnormal levels of radioactivity (see table 19).

Subsurface temperatures in selected wells were measured with a thermistor-Wheatstone bridge combination capable of measuring temperatures with a precision of  $\pm 0.1$  degree Celsius at depths of 3,000 feet (table 31).

## DATA

Tables 1-27 are presented in an identical format. Table numbers correspond to hot-spring areas shown on figure 1. Column headings, location numbers, and abbreviations that are not self-explanatory are described below.

The station number is based on the grid system of latitude and longitude. The station number consists of 15 digits. The first 6 digits denote the degrees, minutes, and seconds of latitude; the next 7 digits denote the degrees, minutes, and seconds of longitude; and the last 2 digits form a sequential number for stations within the same 1-second grid. Thus, if two stations have the same coordinates for latitude and longitude, sequential numbers 01 and 02 are assigned.

Station letters identify the data according to source (station name). Station letters and the date of sample collection are continued for each line of data in the tables to facilitate identification of the source of the sample.

Local station-location numbers are shown to the right of some station names. The location numbers are based on the Federal system of land subdivision. The first number indicates the township north (N) or south (S) of the Montana base line; the second, the range east (E) or west (W) of the principal meridian; and the third, the section. The first letter following the section number denotes the quarter section (160-acre tract); the second, the quarter-quarter section (40-acre tract); and the third, the quarter-quarter-quarter section (10-acre tract). Letters are assigned in a counterclockwise direction, beginning with "A" in the northeast quadrant. Consecutive numbers beginning with 2 are added if more than one station is located within a 10-acre tract. For example, hot spring 04N19W07DCD2 is the second station inventoried in the SE<sub>4</sub>SW<sub>4</sub>SE<sub>4</sub> sec. 7, T. 4 N., R. 19 W.

Abbreviations used in column headings of tables 1-27 are:

AC-FT	Acre-feet
CFS	Cubic feet per second
DEG C	Degrees Celsius
FT	Feet
GPM	Gallons per minute
MG/L	Milligrams per liter
MICROMHOS	Micromhos per centimeter at 25° C
PC/L	Picocuries per liter
UG/L	Micrograms per liter

Codes used in the column SAMPLED BY are:

FR	R. O. Fournier and E. C. Robertson, written commun.
H	Hackett and others (1960), table 31
K	Kaczmarek (1974), table 3
M	Mariner, Presser, and Evans (1976), tables 1, 2.
MBMG	Montana Bureau of Mines and Geology.
MSBH	Montana State Board of Health (now Montana Department of Health and Environmental Sciences).
RFS	Robertson, Fournier, and Strong (1976), table 2 and unpublished data.
USGS	Data collected for this report.
