USE OF CONTINUOUS SLIM HOLE WIRELINE CORING SYSTEMS
ON THE SALTON SEA SCIENTIFIC DRILLING PROGRAM (SSSDP)

The following topics are the subject of discussion in this report.

1. SUMMARY COMPARISON OF CONVENTIONAL VERSUS CONTINUOUS
    WIRELINE CORING

2. ENGINEERING AND CONCEPTUAL DESIGN BASIS FOR THE
    EVALUATION

3. WHAT ARE THE DESIGN AND OPERATING FEATURES OF
    CONTINUOUS WIRELINE CORING?

4. WHAT TECHNICAL OR PRACTICAL LIMITATIONS ARE INVOLVED
    FOR SAFE COMPLETION OF A HOLE SUCH AS THE SSSDP?

5. WHAT ADAPTATIONS OR BREAKTHROUGHS WOULD BE REQUIRED?

6. WHAT SORT OF DEVELOPMENT PROGRAM WOULD BE REQUIRED,
    WHAT ARE ITS ESTIMATED COSTS, AND DEVELOPMENT TIMETABLE?

7. A SHORT REVIEW OF U.S. CONTINUOUS WIRELINE CORE
    DRILLING CONTRACTORS THAT HAVE PARTICIPATED IN CORING
    IN GEOTHERMAL ENVIRONMENTS

8. A REVIEW OF LONGYEAR'S NEW 10,000 FOOT DRILL RIG

9. COMPARATIVE COST OF DRILLING AND CORING FROM 6,000 TO
    10,000 FEET USING THE CONVENTIONAL OIL FIELD ROTARY
    METHOD AND CONTINUOUS WIRELINE CORING METHOD

10. CONCLUSIONS

1. SUMMARY COMPARISON OF CONVENTIONAL VERSUS CONTINUOUS WIRELINE CORING

A. Core Versus Cost

	Conventional Rotary	Continuous Wireline
Probability of reaching 10,000 ft	Very high (95%+)	Low (50%)
Potential core recovery (30 ft cores/60 ft cores)	800/1,600	4,000
Core diameter	4 in.	2.5/1.7 in.
Estimated time to drill from 6,000 to 10,000 ft	65 days	64 days
Estimated cost*	$576,000	$810,400

*Includes rig, fuel, mud, drilling tools, casing and cement.

B. Additional Requirements for Continuous Wireline Coring

1. Extra mobilization and demobilization
2. 25 to 30 ft high substructure lease required
3. 5 in. casing (6,000 ft) and cement (250 ft minimum)
4. 4 in. casing (7,500 ft) and cement (2,750 ft minimum)
5. 3,750 ft of 101 mm drill rod expended
6. 5,000 ft of 76 mm drill rod expended

C. Dimensional Limitation of Continuous Wireline Cored Well

1. 2.98 in. diameter wellbore is inadequate for Kennecott flow test (5 in. minimum is required).

2. Sandia's temperature, pressure, and flow logging tool (3 in. diameter, 8 ft length) can be lowered only to 7,500 ft

3. Los Alamos' fluid sampler (3.5 in. diameter, approximately 10 ft length) can be lowered only to 7,500 ft before 4 in. casing (3.476 in. ID, 3.351 in. drift) is set and can not be put down the hole at all after the casing is set.

4. Placing the 5 in. and 4 in. casing strings in the well, especially if they must be cemented to the surface, seriously limits any options Kennecott might wish to exercise for latter commercialization of the well or for the science groups to test drilling or logging tools.

D. Technical Features of Continuous Wireline Coring
   Creating Engineering Concern and Requiring Further Study

Small flow rates (small flow annuli) and no flow during core retrieval
could have the following effects:

o   Limit cooling effectiveness and encourage metal
    corrosion and fatigue failure. (Frequent inspection of
    drill rods will be required to identify and remove
    damaged or cracked rods. Half of the 101 mm and 76 mm
    drill rod strings are expected to be scrapped at the
    completion of the job. The core retrieval cable may
    have to be replaced during the job.)

o   Wellbore temperatures near the surface may get high
    enough during extended periods of no circulation to
    create a high potential for flashing, requiring the use
    of a core unloading chamber at the surface. Core
    retrieval rates might have to be reduced as well.

o   Cuttings removal could be ineffective, resulting in
    frequent sticking of the drill string

o   Relatively small zones where the formation took fluid
    could result in lost circulation. The typical
    materials pumped down the drill stem bore to block off
    the formation and reestablish circulation could clog
    the annuli in the continuous wireline coring system
    instead.

2. ENGINEERING AND CONCEPTUAL DESIGN BASIS FOR THE EVALUATION

The base case used in the analysis is that the well would be completed to 6,000 ft by conventional rotary drilling and coring. Bechtel estimates that this point would be reached in early November. Continuous wireline coring would then ensure using the Longyear HD600 system. One of these rigs has been built for export to South Africa. Longyear has indicated that they would build a second of these rigs were they to receive an award for the job and believe they could have it operational in about 2 months. The mast is 80 ft, enabling the rig to handle triple stands (60 ft) of drill rod. Core length would be 20 ft. The substructure is only 8 ft high. The hoist capacity is 85,000 lb, but the limiting load handling capacity is that of the drill string feed control system which is 60,000 lb.

The specifications of the drill rods and core barrels are shown in Table I, reproduced from the most recent Longyear brochure. These are the "standard" sizes used in the industry.

Table I

Specifications

	Metric			English		
	CHD 76	CHD 101	CHD 134	CHD 76	CHD 101	CHD 134
Hole Diameter (Regular)	75.7 mm	101.3 mm	134.0 mm	2.980 in	3.990 in	5.250 in

Inner Tube ID	45.3 mm	66.9 mm	88.9 mm	1.781 in	2.635 in	3.500 in

CHD rods are available in 1.5 m, 3 m, 4.5 m and 6 m lengths, or 10 ft and 20 ft lengths.
Standard core barrel lengths are 3 m and 6 m. Special length on request.
Note: 1. Specifications are subject to tolerances and are therefore approximate.
2. Depth ratings are based on straight, vertical, clean, fluid-filled holes.

(A special 6-3/4 in. drill rod was fabricated for Norton-Christensen several years ago for use on a hazardous waste injection well in Nevada. The project was cancelled and the 3,000 ft of rods were never used. The small quantity available and high weight of approximately 25 lb/ft makes it unusable for the SSSDP).

The weight of the drill rods, the maximum length of drill string that could be used on the Longyear rig, and the associated costs are shown in Table II.

<p align="center">Table II</p>

Drill Rod Type	Lb/ft for 20 Ft. Rods	Maximum string length at 60,000 lb*	Cost per Foot	Cost for String
CHD 134	13.10	4,800	$27.50	$132,000
CHD 101	8.53	7,400	$20.10	$149,000
CHD 76	5.56	11,300	$14.20	$142,000**

* Bouyancy factor = 0.859 for 9.2 lb/gal mud; Drag = 10%
** To 10,000 ft

The 60,000 lb weight limit precludes use of the 134 mm (5 in.) drill rods in the SSSDP well. Coring would have to be started at the 6,000 ft casing point to about 7,500 ft with the 101 mm (3.875 in.) drill rods, switching to the 76 mm (2.875 in.) drill rods from there to total depth. If the 101 mm string got permanently stuck before reaching the 7,500 ft limit, the 76 mm string would be inserted through the 101 mm string, the 101 mm drill head reamed out, and coring continued on until the 76 mm string reached total depth or got stuck. Using the Longyear rig, and the 101 mm and 76 mm strings, the driller could only get permanently stuck twice before operations would have to be discontinued or side tracking the hole attempted.

Other coring rigs with weight capacities suitable for using the 134 mm (5 in.) drill rods from 6,000 ft to total depth exist in the United States and could be outfitted for use on the SSSDP if suitable time were
available. Tonto Drilling, one of the leading independent wireline coring contractors, expressed interest in this alternative. It would take them about four months to locate, overhaul, and be ready to mobilize such a rig. If Bechtel could award a contract for continuous wireline coring by September, the larger rig would not be ready until January, two months later than required. Being able to start coring with the 134 mm and to run both that and the 101 mm string to total depth would have been a much preferable position to be starting from on this first-of-a-kind application for continuous wireline coring.

The conceptual design for a coring program using the Longyear rig is shown in Figure 1. In summary, a 5 in. casing would be installed from the surface to 6,000 ft to guide and support the 101 mm string. At a minimum, the bottom 250 ft (5,780 ft well depth) would have to be cemented in to provide blow out protection. Ideally, it would be cemented to the surface. With only 250 ft cemented, the 9-5/8 in. BOP stack would be kept in place as a precaution during the continuous wireline coring operation. The 5 in. casing would be set by the rotary drilling contractor just prior to demobilization and move out. At 7,500 ft, a 4 in. casing would be cemented back to 5,750 ft to guide and support the 76 mm string. The 4 in. casing string would be set using the coring rig. If the 10,000 ft target depth were reached, the final well configuration would have 7,500 ft of 4 in. (3.476 in. ID, 3.351 in. drift) cased hole and 2,500 ft of 2.980 in. open hole.

The combination of the 9-5/8 in. BOP stack and the BOP for the coring strings would be about 30 ft tall. The Longyear rig would have to be mounted on a substructure at least 25 ft high. This would require that a suitable substructure be fabricated or leased from a rotary drilling contractor willing to idle his rig during the coring period.

During coring, the annuli between the drill string and the borehole and the core barrel and the core retrieval tube are quite small. As shown in Figure 1, Section A-A' and B-B', the downflow annulus on the 76 mm system

NOTE :

THIS CONFIGURATION WOULD OCCUR DURING CORING FROM 7,500 FT. TO FINAL DEPTH. FORMATION TEMPERATURES RANGE FROM 675 ° F TO ABOUT 715 ° F IN THIS INTERVAL. MAXIMUM CIRCULATION RATES FOR COOLING AND CUTTINGS REMOVAL ARE LIMITED TO ABOUT 15 gpm., PASSING THROUGH AN EQUIVALENT TUBULAR FLOW AREA , SHOWN ABOVE TO THE LEFT. DURING CORE RETRIEVAL, CIRCULATION IS NORMALLY STOPPED.

is 0.125 in. (total areas for flow = 0.83 in.^{2}) and the return annulus
is 0.05 in. (total area for flow = 0.45 in.^{2}) until entering the final
6,000 ft where it increases to 0.72 in. (total area for flow).

Typical circulation rates used by Longyear while coring are 7 to 10 gpm,
with a practical maximum of about 15 gpm. A calculated pump pressure of
approximately 600 psi would be required for 15 gpm flow in the well as
shown. Theoretically increasing the flow to 25 gpm would require a pump
pressure of about 1,500 psi. At 50 gpm, the pressure requirement would
increase to about 6,500 psi. The maximum rating on the standard Longyear
pump is 35 gpm @ 1,000 psi. During core retrieval, circulation is
normally stopped. Round trip time at 9,000 ft., for example, is
estimated at 130 minutes, under normal circumstances. During this
period, the drill string would be exposed to formation temperatures and
any brines which entered the well bore.

The average expected coring rate from 6,000 to 10,000 ft is estimated at
about 2.6 ft/hr, based on total time from mobilization to demobilization,
and about 3.25 ft/hr when coring. If the core retrieval rate must be
reduced to control downhole flashing, the average coring rate would have
to be adjusted downward.

3. WHAT ARE THE DESIGN AND OPERATING FEATURES OF CONTINUOUS WIRELINE CORING?

   A. Potentially 100 percent of the hole is cored.

   B. A relatively large core is taken compared to hole size, generally resulting in a very good percentage of core recovery in most rock formations. For example, with 101 mm system holes size (3.895 in.) core size is 2.500 in. or for 76 mm system holes size (2.980 in.) the core size is 1.713 in.

   C. In harder formations, much faster core penetration rates result because of the narrow kerf of the diamond bit.

   D. Very accurate feed control and high rotator speeds (500 - 750 rpm) increase core recovery and penetration rates while coring.

   E. Core is extracted by pulling the inner barrel laden with core through the string of pipe to the surface with a wireline. This allows for almost immediate review of the recently cored material, and since the rods do not have to be removed each core trip, there is less chance of hole deterioration. Because it is easy to pull and check core in the inner tube, a core blockage or short run can be easily tripped to the surface and checked rather than continuing the run and losing core. Continued grinding of a broken core decreases bit life, core penetration rates, and most important reduces core recovery.

F. Because of the system's small size and weight, it
    requires much less rig horsepower, both in hoisting and
    rotating, and has smaller fluid systems requirements.
    Hence, rigs are generally much smaller in physical
    size, and in most cases the rigs are run with much
    smaller crews. However, in the case of the SSSDP, the
    crew size could be almost as large as on a conventional
    oil rig.

G. The thin walled drill rods (0.25, 0.129, and 0.19 in.)
    and small annuli (0.125, 0.145, and 0.113 in.) reflect
    a design optimization for coring in crystalline rock
    for minerals explortation. Under these circumstances,
    the borehole supports the drill string and provides
    stability. The smooth, nonpermeable borehole wall
    efficiently conducts the cuttings to the surface with
    little or no fluids loss to the formation.

4. WHAT TECHNICAL OR PRACTICAL LIMITATIONS ARE INVOLVED FOR SAFE COMPLETION OF A WELL SUCH AS THE SSSDP?

   A. One-Way Valves. A wireline drill rod string is open from the coring bit to the circulation swivel; there are no one-way fluid valves in the pipe string as would be used in conventional systems. This eliminates one of the normal safety features. Careful planning and management of well control would be required.

   B. Pipe Wear and Corrosion. The continuous wireline coring system relies on high alloy (4130 heat treated tool joint, tensile strength 125,000 psi and 1035 or 4130 mid body, 90,000 psi) for high strength with low weight. Thin wall tubing with thicknesses from 0.188 to 0.219 in., do not lend themselves to exterior wear, stress cracking, and corrosion that will likely occur in the high temperature, saline environment. Drill rod failure may be considerably more frequent then in non-geothermal wells, in spite of best efforts to inspect frequently.

   C. Poor Well Cooling. While retrieving core, circulation is normally stopped, allowing the stagnant wellbore fluids to heat up and cuttings to settle out. As the hole gets deeper, you will be spending more time retrieving the inner tube laden with core than will be spent coring a 20 ft run. Continuous fluid circulation while extracting core through the string is highly desirable, but may not be physically possible. At 9,000 ft, circulation could be interrupted 130 minutes or more. Table III is an estimate of time required for making a complete core cycle in a 9,000 ft hole. At temperatures approaching 700°F, the strength of the drill rods decreases about 10 percent. Some additional development and planning must be worked out to accommodate this condition.

Table III

a. Insert core retrieving overshot

    0 - 9,000 ft   30 min

b. Retrieving inner tube with core

    9,000 - 0 ft   40 min*

c. Inserting new inner tube and
    circulating to aid drop time

    0 - 9,000 ft   40 min

d. Adding pipe connections and
    disconnecting extras   20 min

Total Time = 130 min

Time spent pumping inner tube   -40 min

Time when hole is not being circulated 90 min

Estimated Core Time per 20 ft
core run   60 min

The 90 minute period where there is no
circulation could present hole problems due to
not moving the fine cuttings to surface plus not
continuing to cool with circulating fluid.

* Assumes approximately 200 ft/min retrieval rate.

D. Mud Cleanup System. Because of the very small annulus between
    hole and drill pipe, low fluid volumes are used (about 15 gpm
    maximum for the 76 mm string). Additional fluid volume at depth
    only increases fluid pressure and could direct fluid into the
    formation, rather than up the hole. Reverse circulation may have
    the same effect. When circulation is stopped during core
    retrieval, cuttings may settle out of the mud column and
    accumulate in the bottom of the hole. It becomes very important
    to get these cutting out of hole and that the mud and fluid
    systems do not break down at the temperatures and pressures
    expected. The use of desilters and deslimers plus large return
    mud tanks would be a must to minimize the chances of differential
    sticking of the drill pipe.

E. Supplementary Cooling Options. It may be necessary to supercool
    all fluids entering the hole, plus use larger return tank-system,
    cooling tower or heat exchanger to aid in cooling before reentry
    to the hole. These large tanks might also be used to reduce
    solids in the return fluid.

F. H_2S Embrittlement. There is a possibility of hydrogen (H_2S)
    embrittlement, which could adversely affect the wireline and
    drill rod. They are already at a lower factor of safety at total
    depth of 2 to 1, whereas conventional API pipe has a 3 to 1
    factor of safety. H_2S may not be encountered, however, because
    of the amount of free metal ions in the brine. But since this
    type of drill pipe has never been used in this environment, at
    this depth, H_2S should be carefully monitored.

G. Small Retrieval Cable. The continuous wireline coring system
    relies on a small diameter cable (3/16 in., 0 to 3,000 ft,
    1/4 in., 0 to 5,000 ft, 3/8 in., 0 to 10,000 ft) to retrieve
    core-laden inner barrel from the bottom of the core hole. This
    means that the wireline cable is subjected to the effect of brine
    as well as very high temperature. It may not be a major problem,
    but it is another consideration that must be planned for and
    constantly watched, in an effort to reduce rope failure that
    could shut down the core drilling process.

H. Core Barrel Life. Continuous wireline core barrels and
    associated parts do not seem to present any additional problems
    that would not exist with the conventional or field core
    barrels. There are however, more mechanical working parts to be
    considered, even though these barrels have functioned well in the
    shallow geothermal holes. Corrosion and abrasion could present
    the major problems with these systems and would require the
    operator to replace parts more often or set specific maximum
    footage or rotating time limits for each complete core barrel.

I.   Bit Life. Diamond bits used in continuous wireline coring
     systems at the temperatures in question appear to be state of the
     art. All diamond bit manufactures questioned do not view 400°C
     as a major problem.

J.   Logging Tool Diameters. Fluid sampling, wireline logging,
     temperature measurements and flow information can be gathered
     through the 134 mm and 101 mm boreholes. The 76 mm (2.98 in.)
     borehole may restrict the use of larger tools. However, through
     the drill string logging has not been done at the depths or
     temperatures in question by a continuous wireline core contractor
     to date.

K.   Blow-out Preventors. Continuous wireline contractors have used
     blow-out preventors (BOPs) in the past, and their use is not
     envisioned as a problem. However, the availability of smaller
     specialty BOP's may be limited.

L.   Directional Control. The core-drilling industry over the years
     has been able to maintain hole straightness through the use of
     packed-hole core barrels (core barrels that have been fitted with
     special stabilizers that are very close to hole gauge), by
     increasing or decreasing rotational speeds, and by carefully
     watching the weight on the diamond bit. Traditionally, deviation
     hasn't been a major problem in crystalline rock. There may be a
     tendency to drift in the sedimintary formation in the Imperial
     Valley. Typically, hole correction has been done with similar
     tools as those used in the oil field, such as Nave Drill, Dyna
     Drill or whip-stock methods. There has never been any
     directional or corrective drilling done at temperatures or depths
     that are remotely near the ones that maybe encountered in the
     SSSDP.

M.   Hole Flashing Problems. Initially hole flashing problems were of
     concern due to high downhole temperatures. After consideration
     it seems to be more of a problem near the surface than at the
     bottom of the well. There is still some concern that the very

low fluid circulation rate of the wireline system may allow the
well to get hot enough near the surface that flashing could be
induced during core retrieval and perhaps even during rotary core
tripping. This needs more extensive analysis.

ANALYSIS OF FLASHING POTENTIAL IN THE LOWER PORTION OF THE SSSDP WELL

	Estimated Temperature °F	Hydrostatic Head @ 0.4775 psi/ft. (Mud weight 9.2 /gal)	Flash Point of Water	Pressure Drop Required for Flashing
6,000 ft	660	2,865	2,340	525
7,000 ft	670	3,342.5	2,520	823
8,000 ft	680	3,820	2,700	1,120
9,000 ft	690	4,297.5	2,880	1,417
10,000 ft	715	4,775	3,240 (vapor)	-

5. WHAT ADAPTATIONS OR BREAKTHROUGHS WOULD BE REQUIRED?

    A.   Develop a loading chamber system atop the drill string so that the core laden tubes can be isolated from the heat and pressure of the hole during core removal. The operation method used at present subjects personnel to some potential safety problems if flashing occurs.

    B.   Conduct a complete test of continuous wireline core retrieving cables under Salton Sea brine conditions. The main concern is the effect of corrosion on cable performance.

    C.   Subject continuous wireline core drilling pipe and core barrels to some simulated wear and corrosion tests to indicate rotating hour life for safe operation.

    D.   Develop a system to continue to circulate sufficient volumes of fluid while coring and retrieving core to help keep the hole temperature down and to keep the solids moving to the surface for hole cleaning.

    E.   Previous drilled rotary holes in the Salton Sea area indicate very high drag forces in both torsional and tension, in some cases as much as 100,000 lb above the string weight. Continuous wireline core pipe could be subjected to proportional testing to simulate these conditions.

    F.   In the long run, develop larger diameter drill rods and rigs to reach greater depths.

6. WHAT DEVELOPMENT PROGRAM WOULD BE REQUIRED, WHAT ARE ITS ESTIMATED
   COSTS AND DEVELOPMENT TIMETABLE?

   A. Suggested development program:

      1. It appears that the interest is very high toward the
         continuous wire line coring methods. Demands on existing
         systems that were designed for the mineral industry have
         expanded to geothermal, gas, oil and scientific programs,
         many of which demand special disciplines. With this in mind,
         it is suggested that a committee be established consisting of
         core drill manufacturers, core drilling contractors,
         interested rotary manufacturers and contractors, oil and
         mineral companies, plus those companies and individuals who
         need, use, or have expertise in these disciplines. This
         should include government agencies.

      2. Suggest the above committee or group start by working on
         problems that are outlined in No. 3 listed earlier.

      3. Perhaps a government grant through a research or engineering
         group could provide funds to actually set up a field testing
         program.

   B. Estimate costs of development type of program:

      Any estimate at this point is speculation, but a $500,000
      program should get the existing drilling system up to speed
      in all areas.

   C. Timetable that must be required:

      A timetable that would cover those conditions as tests in
      No. 3 might be accomplished in as short as 9 months to as
      long as 15 months.

7. A REVIEW OF U.S. CONTINUOUS WIRELINE CORE-DRILLING CONTRACTORS THAT
HAVE PERFORMED DRILLING SERVICES IN GEOTHERMAL ENVIRONMENT

The experience of U.S. contractors is summarized below:

| Contractor | Geothermal Wells | | | Deepest Hole Under |
	No. Holes	Max Depth	Max Temp	Mineral Conditions
Tonto Drilling Services Size	30	4,000 ft	350°F	6,900 ft - 'H'
Longyear	18	3,000 ft	390°F	7,100 ft 101 MM
		3,000 ft	490°F	7,400 ft 'B' Size
Boyle Bros Drilling	2	2,800 ft	-	6,100 ft 'N' Size
Himes Drilling Co. Inc.	2	2,800 ft+	-	- - - - - - - - -

This review reveals that two (2) contractors have done, by far, the
majority of the drilling. Tonto Drilling Services has drilled the
deepest hole, 4,000 ft, while Longyear has drilled in the hottest
environment (reportedly 390°F). Mr. Dick Swayne, Manager of Longyear's
Contract Drilling Division, has reported that 490°F was encountered in
China Lake Well No. 5. The above table also shows the maximum depths
that each contractor has drilled under normal mineral drilling conditions.

A review of the work done to date reveals that these U.S. contractors
have not had any drilling experience in super-high temperature
geosolution, nor have any reached the 10,000 ft depth requirements that
are planned in the SSSDP.

The majority of continuous wireline core drilling contractors have been
very successful drilling geothermal holes 3,000 ft to 4,000 ft deep that
have a loose circulation condition (no return circulation). Under this
condition the core drillers using the continuous wireline method were
able to advance the hole in the blind condition plus recover the core.
Wireline core systems allow these holes to be continued and bottomed,
whereas the conventional rotary equipment made hole advancement extremely
difficult and very expensive.

8. A REVIEW OF LONGYEAR'S NEW 10,000 DRILL RIG

   Derrick - 80 ft extended
              43 ft retracted
              60 ft (triple) stands
              API Rated at 100,000 lb
              Crown sheaves rated at 100,000 lb
   Draw Works - Hydrostatically driven with automatic release on
              drum while coring. Built-in spring loaded brake
              system for static holding only. Drum 24 in. OD with
              rope grooving. Load handling through 6 part line
              using 7/8 in. rope, giving maximum hook load of
              85,000 lb.

   Line Speed Bare Drum - 6 part line
              High 1,356 ft/min - 226 ft/min hook speed
              Low 498 ft/min - 83 ft/min hook speed

   Top Drive Head and Feed System
              60,000 lb hold back load while coring
              Head can chuck 3-15/16 in. when drilling over 5,000 ft
              a Hex Ring Kelly System is used through the top drive
              head to handle maximum weight condition.

   Rated Capacity of the Drill Unit in a Fluid Filled Hole
              CHD - 134 mm = 5,000 ft
              CHD - 101 mm = 7,500 ft
              CHD - 76 mm = 11,500 ft

A quick review of the above specifications reveals that the 60,000 lb
maximum hold back feed system is the limiting depth factor of this
drill rig. Though the hoist has more capacity, 85,000 lb, it cannot
be used in the feed or rotating mode, hence the drill's capacity is
limited to 60,000 lb. You can theoretically drill a 10,000 ft hole,
but this hole must be done with 76 mm size 2-3/4 in. OD pipe in a
3 in. OD hole. In the case of the Salton Sea hole, you would
seriously limit your alternatives because you do not have the option
of starting the coring with the larger 134 mm system. From a hole
engineering point of view, you should maintain the largest size
system until required to reduce due to in-hole conditions. This
allows you the safety of continuing the hole with 101 mm, leaving you
the option of an additional reduction to 76 mm to assure completion
to 10,000 ft total depth. (Detailed drill rod specifications are
presented on the following page.)

DRILL ROD SPECIFICATIONS

	76 mm	101 mm	134 mm
Rod OD	2.75" (69.8mm)	3.701" (84.0mm)	57 (137mm)

Weight of 6 metre Rod	110 lbs.	165 lbs.	262 lbs.
Standard Core Size	1.713"	2.5" (HQ)	2.244" (PQ)
Standard Hole Size	2.98"	3.99"	5.250"
Midbody Material	Grade 1035 or 4130	Heat Treated UTS	- All CHD the same
Joint Material	Grade 4130	Heat Treated UTS	- All CHD the same

It is understood this drilling unit was designed for South Africa, which has a requirement of drilling to 10,000 ft, and the maximum hole size in that part of the world is 2.98 in. OD using the 76 mm system. So while the drill meets the depth requirements, it does not allow the additional hole size and depth alternatives that may be needed to meet hole conditions that could be present on the SSSDP.

Per Mr. Dick Swayne of Longyear Co. the following is a typical hole that was recently drilled in New Mexico on an Oil Gas exploration well.

        Rotary 0 - 900 ft, 9 7/8 in. bit
            900 - 2,500 ft, 7 7/8 in. bit

        Casing 0 - 2,800 ft, 6 5/8 in. Casing

        Coring 2,500 - 4,000 ft, 134 mm - 5 1/2 to 6 in. bit

        Casing 0 - 4,000 ft, 5 in.
            4,000 - 7,000 ft + 101 mm - 4-3/8 in. Bit

        Rotary Pump - GD - 5-1/2 in. x 8 in.

        Core Pump Bean Twine Model 835
                    Hydrostatically Driven
                    10 to 70 GPM @ 850 PSI

Ideal Core Rig Capacity. From a continuous wireline coring point of view the drill rig should have the capacity to handle both hoisting, rotating and feeding of the 134 mm string to the maximum depth of 10,000 ft. If in hole conditions didn't demand casing, it would be to the advantage of the program not to case and change hole size. However if the hole condition required casing and size reduction, we have that alternative available, plus an addition size smaller as a last resort.

0 - 10,000 ft	134 mm System	131,000 lb
0 - 10,000 ft	101 mm System	85,300 lb
0 - 10,000 ft	76 mm System	55,600 lb

It would appear the drill rig with a hook load capacity of 225,000 lb would be more desirable plus have feed and rotating capacity of 150,000 lb to handle the 134 mm system to the 10,000 ft depth.

9. THE COMPARATIVE COST OF DRILLING AND CORING FROM 6,000 TO 10,000 FT USING THE CONVENTIONAL OIL FIELD ROTARY METHOD AND CONTINOUS WIRELINE CORING METHOD.

The proposed approach would have the first 6,000 ft drilled conventionally and cased. The rotary unit would drill through the high pressure gas zone and set the 9 5/8 in. casing to 6,000 ft. After completion, this same rig could set the 5 in. casing string for use with the 101 mm system.

The following are some of the cost considerations:

A. There are move-in move-out costs for the rotary drill, as well as the core drill. For the coring part of the hole, Longyear estimates these costs to be approximately $100,000.

B. The rotary drill substructure should be left in place to accommodate all of the BOPs needed. A review of the hole casing plan for the rotary indicates 9-5/8 in. production casing with its normal BOP stack plus wireline coring 5-1/2 in. casing to accommodate CHD-101 mm wireline coring system plus 4 in. casing string to accommodate CHD 76 mm wireline coring system. These casing and drilling strings will require a BOP stack.

The substructure of oil rotary rig has sufficient clearance, 25 to 30 ft, to accommodate these BOP stacks, but the Longyear coring rig only has about 8 ft clearance. The Longyear drilling rig is of modular design, so it can be easily mounted on the deck of the substructure without its subbase but would require a rental crane to mob and demob. Additional arrangement must be made with the rotary contractor to lease his substructure during the coring operation. The cost of the substructure has not been included in the wireline coring estimate.

C. Coring costs will increase as a result of only drilling the lower part of the hole for the following reasons:

1. Mob and demob would be the same as if started from
    0 to 10,000 ft, but you can only write off this cost
    against 4,000 ft of drilling.

2. Under this scenario the contractor will be required to
    have two (2) strings of pipe 101 mm 0 to 7,500 ft and
    76 mm 0 to 10,000 ft and must write off wear and cost
    over only 4,000 ft of drilling, though he is required to
    invest a very large amount for the entire string of pipe.

3. This method requires a very large core drilling rig
    because of depth and size, and all the related costs of
    the large rig must be written off against a small amount
    of footage drilled.

4. If this hole is planned to be used for production, there
    is a good chance that these small strings of casing or
    stuck rods could not be removed, or if so it might be
    done at a substantial cost. The small core drill does
    not have hoist capacities to remove the 5 in. casing
    string that was set by the rotary. In order to rework
    the hole for production, a remob of the rotary drill may
    be required.

The following pages show a rough cost estimate for continuously wireline
coring the SSSDP from 6,000 to 10,000 ft and a comparable Bechtel
estimate for conventional rotary drilling and coring. The continuous
wireline coring estimate is about 30 percent higher.

Continuous Wireline Coring $810,365

Conventional Rotary Coring and Drilling $576,050

10. CONCLUSIONS

From an engineering point of view there is no question in my mind that if hole completion is important, the rotary oil rig with all its proven systems and its excess capacities would assure one of successfully completing this hole to 10,000 ft. However, from a scientific point of view one could certainly obtain additional scientific information by continuous wireline coring in areas where presently there is limited information.

One must weigh using the continuous wireline method against the following facts.

A. The 10,000 ft core drilling rig presently being built by Longyear has never attained that depth.

B. No continuous wireline coring contractor in the United States has personnel that have drilled to 10,000 ft nor at temperatures close to those that will be encountered at the Salton Sea Project.

C. Wireline core drilling tools have been subjected to geothermal environments but none have been subjected to such high temperatures or possibly as corrosive and abrasive geothermal solutions as will be encountered in the 10,000 ft Salton Sea hole.

D. Because of the very close tolerances between hole size and casing used, cementing holes could present real problems. Add to this condition 400°C hole temperatures plus brine solutions, and cementing may be impossible. At any rate, as of now, it is an unknown for the wireline core driller.

E. I have a serious concern with the continuous wireline core method in the following areas:

a. Corrosion

b. High drag forces (torsional and tension)

c. Wear

d. Temperature

e. Very low fluid volumes used in drilling present some
safety questions

f. Hole deviation because of in-hole conditions that are
different (sedimentary formation versus granitic
formation) where most of wireline work has been done
using the continuous wireline core method

The task of deep wireline core drilling is not impossible.
However, there are certainly many unknown conditions in the
Salton Sea project, that the wireline core drilling contractors
would be eager to start solving. To do so in a timeframe that
would assure completing the hole to 10,000 ft may take from 9 to
15 months of development work prior to beginning drilling.

There are two things that tend to assure hole completion:

1. Seasoned personnel that have drilled in these conditions
to the proposed depths with support people they are
familiar with

2. Proven rigs, tools and support systems

In view of the task at hand, it would appear that the continuous
wireline coring system needs the support of a separate research
program.
