NOTE: Volume II of this report contains individual state maps depicting inventoried cities and hydrothermal resources.

I. ABSTRACT

Eight states in the western U.S. are inventoried to identify incorporated cities located within five miles of a thermal well or spring having a temperature of 50° F or greater. Inventoried states include: Alaska, Arizona, California, Hawaii, Idaho, Nevada, Oregon, and Washington.

The inventory identifies a total of 1,277 hydrothermal sites within five miles of 373 cities in the eight states, with a combined population of 6,720,347 persons. The combined heat load for all cities (exclusive of industrial loads) is estimated at $132,558.0 \times 10^9$ Btu/yr.

The inventory appears in two volumes, the first being this report, and the second containing individual state maps of identified cities and hydrothermal sites.

II. OBJECTIVES & METHODOLOGY

A. OBJECTIVES

The objective of this report is to provide a preliminary inventory of cities in eight western states which are proximate to a confirmed hydrothermal resource, and to tentatively identify their population growth and heating load characteristics. The states inventoried include: Alaska, Arizona, California, Hawaii, Idaho, Nevada, Oregon, and Washington.

This inventory is the first known region-wide compilation of incorporated population centers possessing proximate (5 mi. or less) hydrothermal potential for direct-use or heat pump application. As such, it is intended as a preliminary aid for geothermal officials engaged in resource planning and commercialization. Specifically, the identification of municipalities co-located with hydrothermal resources is intended to recognize the significant urban energy value of geothermal resources, and to encourage the formulation and implementation of urban hydrothermal development strategies.

B. METHODOLOGY

This report was prepared under a subcontract from the Oregon Institute of Technology (OIT) Geoheat Center. In specifying the project's work scope OIT requested that cities be inventoried in eight western states based upon two selection criteria:

- 1) That the community or population center in question be an incorporated municipality; and
- 2) That the city in question be located within five miles or less of a thermal well or spring having a confirmed temperature of 50° F or greater.

The report was prepared in accordance with these criteria, except for applying the incorporation prerequisite to sites in Nevada

and Hawaii. In Nevada, many population centers are not municipally incorporated, instead relying on county government for local services; therefore, two unincorporated communities are included in the Nevada sites because of their size and resource potential. In Hawaii, the local government system is even more county-based, with municipal incorporation being very rare; therefore, all identified Hawaiian cities are urban population centers, but they do not exercise any powers of a municipal corporation.

The inventory was compiled using each state's most current and available data describing thermal ground water, population growth, and energy use. The states' thermal ground water mapping was cross-checked against locations of incorporated cities to establish the 5-mile criteria. It should be noted that several well-known communities may not appear in the inventory due to the 5-mile limitation. For purposes of establishing the 5-mile limit distances were measured from city centers, such that some cities may have had outer boundaries within five miles of a resource, but were eliminated because of the greater actual distance to the developed urban center. Many additional cities were found to be within 5 to 15 miles of a confirmed resource; however, the purpose of the 5-mile limit was to identify communities having minimal resource piping requirements, and therefore, increased near-term potential for development. Screening was also performed for the requisite temperature of 50° or greater; the purpose of including resources beneath direct-use temperature requirements was to acknowledge the large potential for ground water heat pump applications.

Identified cities were subsequently described according to: hydro-thermal resource depth and temperature ranges (depth information was available for only five of the eight states); current population

level and annual average growth rate; and by estimated community heating load. These characteristics are intended to tentatively compare resource potential against current and projected population levels, and to indicate the local potential for displacing conventionally-fueled heating loads.

The estimation of community heating loads was performed using a methodology developed at the OIT Geoheat Center (Lund, 1980). This methodology estimates heating load according to two major community land-uses:

1. Residential space heating and water heating; and
2. Commercial space heating and water heating.

The public facility and institutional space and water heating portion of the community load is included within the commercial estimate shown in the inventory tables of Part III. The scope of this inventory precluded estimates of industrial process heat loads in identified cities, so that each community's total estimated heat load is exclusive of any industrial process heat requirements which may be met by hydrothermal energy.

The following sections explain the heat load methodology in detail, as it was applied to the residential and commercial (including public and institutional) sectors.

a) Residential Heating Load

Based upon U.S. Census Bureau data and national homebuilding averages, an average residential structure size of 1,800 square feet and average household size of 2.8 persons were used. Space heating varies according to climate and is therefore a function of the degree days of heating

(DD) and the outside design temperature (T), with a correction factor of C_D . Based upon extensive analysis of heating loads in the Klamath Falls, Oregon area, a peak heating rate of 25 Btu/hr/ft^2 was used for an average home, based upon an older outside design temperature of 0°F . Using the current residential outside design temperature of 4°F , a corrected peak heating load of 23.5 Btu/hr/ft^2 is obtained for the Klamath Falls, Oregon area. Using the following ASHRAE relationship, an annual heating load is given as:

$$\text{SHL} = \frac{\text{Peak Load/hr} \times 24 \times \text{DD} \times C_D}{65 - T}$$

(For Klamath Falls: DD = 6,516 F-days/year, current outside design temperature, T = 4°F , $C_D = 0.74$, and the peak heating load = $23.5 \times 1,800 = 42.3 \times 10^3 \text{ Btu/hr.}$)

$$\text{SHL} = \frac{42.3 \times 10^3 \times 24 \times 6,516 \times 0.74}{65 - 4} = 80.2 \times 10^6 \text{ Btu/yr}$$

An expression can be developed from the Klamath Falls peak load to determine the peak load for any other area, based upon the residential outside design temperature T and the solid line in Figure 1. This relationship is:

$\text{PHL} = 45,000 - 693 \times T$ (in Btu/hr. for an $1,800 \text{ ft}^2$ house). Thus, the annual heating load relationship can be expressed as follows:

$$\text{SHL} = \frac{(45,000 - 693 \times T) \times 24 \times \text{DD} \times C_D}{65 - T}$$

(in Btu/yr)

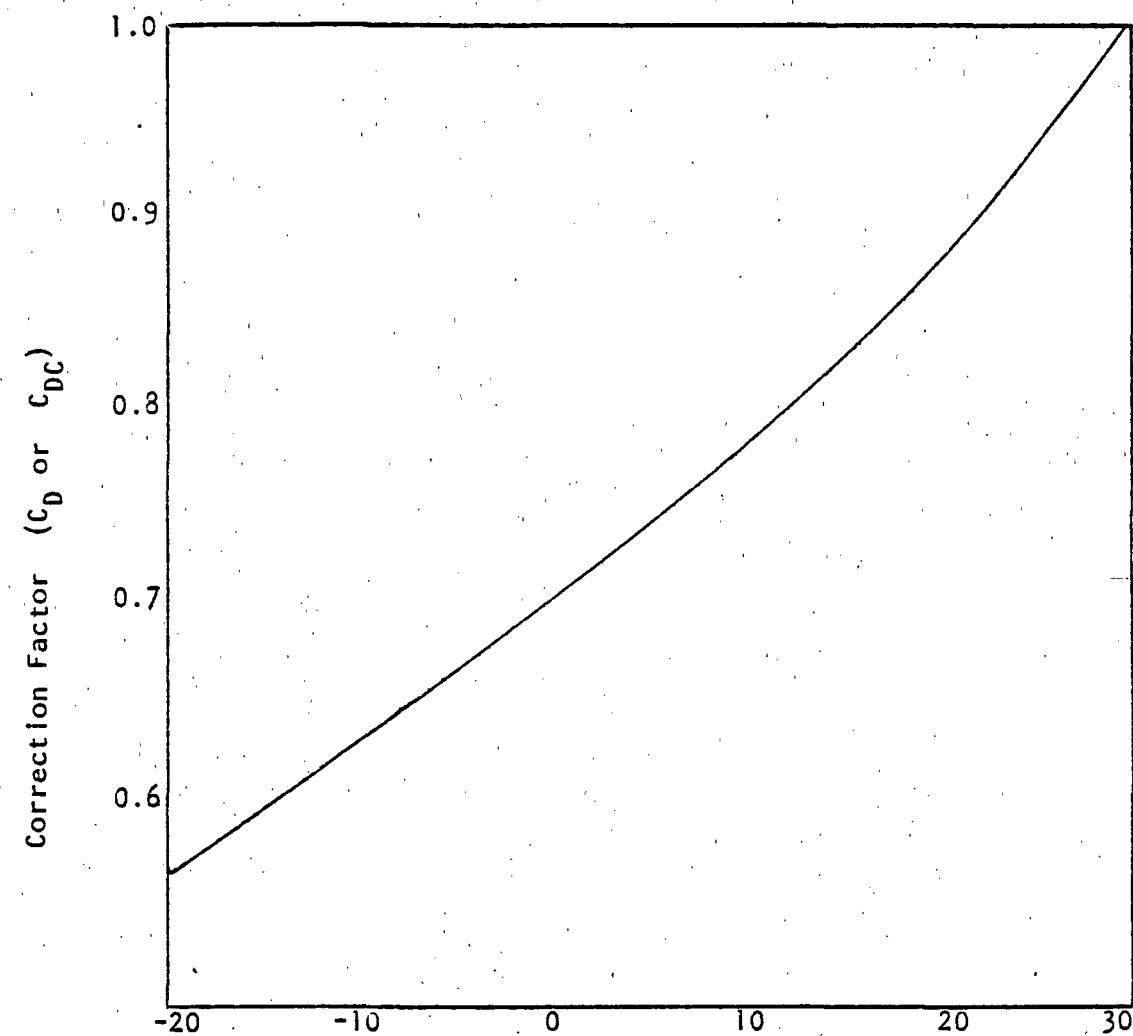

Figure 1.

Outside Design Temperature in $^{\circ}\text{F}$ (T or T_c) adapted from ASHRAE, 1976.

The remaining energy use in an average residence is based upon 1980 utility data collected by the Bonneville Power Administration, which serves five of the eight states inventoried. This energy use includes domestic water heating and other electric appliances. The data for these loads are based upon the following information:

Domestic Water Heating

Single family residence: 4,360 kwhr/yr
Multi-family residence: 3,229 kwhr/yr

All other electrical load (lights, appliances, etc.)

Single-family residence: 7,667 kwhr/yr
Multi-family residence: 6,862 kwhr/yr

Single-family residences account for 74.2 percent of the residences in the five-state region served by the Bonneville Power Administration, and therefore, a weighted average for the foregoing figures are:

Domestic water heating: 4,068 kwhr/yr
All other electric load: 7,459 kwhr/yr

The final factor used in the residential calculation is the penetration or capture rate of electrical energy vs. fossil fuel within a given geographic area. Using the same Bonneville Power Administration data cited above, the following figures represent the electric share of each climate zone:

Climate Zone	Annual Degree Days Heating + Cooling	Electrical	
		Percent Penetration of Water Heating	Percent Penetration of Space Heating
I	6,000	85.4	45.6
II	6,000-7,000	91.0	55.1
III	7,000-8,000	91.0	44.5
IV	8,000	52.6	22.7

Using the above information, the following estimate can be made for a hydrothermal resource site:

1. Electric space heating load:

$$SHL_1 = \frac{(45,000 - 693 \times T) \times 24 \times DD \times C_D}{65 - T} \times \frac{P}{2.8} \times C_h$$

(in Btu/yr)

where:

DD = degree days of heating for the area,

T = outside residential design temperature,

C_D = outside residential design temperature correction factor for the area,

C_h = saturation rate for electrical space heating, and

P = population of area.

2. Fossil fuel space heating load:

$$SHL_2 = SHL_1 \times 1 - C_h$$

C_h

3. Electric water heating load:

$$WHL_1 = 4,068 \times \frac{P}{2.8} \times C_w \quad (\text{in kwh/yr})$$

$$= 4,959 \times 10^6 \times P \times C_w \quad (\text{in Bt/yr})$$

where:

C_w = saturation rate for electrical water heating.

4. Fossil fuel water heat load:

$$WHL_2 = WHL_1 \times \frac{1 - C_w}{C_w}$$

Summary:

Total space heating load:

$$SHL_R = SHL_1 + SHL_2$$

Total water heating load:

$$WHL_R = WHL_1 + WHL_2$$

Total residential heating load:

$$RHL = SHL_R + WHL_R$$

b) Commercial & Public/Institutional Heating Load

Based upon the Klamath Falls, Oregon experience cited above, a value of 33 Btu/ft²/hr peak heating load was assumed using an outside design temperature of 0°F.

A corrected peak heating load of 28.4 Btu/ft²/hr is obtained for Klamath Falls using the current commercial outside design temperature of 9°F. This gives an annual use of ($C_{DC} = 0.78$ for an outside commercial design temperature of 9°F).

$$\underline{28.4 \text{ Btu} \times 24 \text{ hr} \times 6,516^\circ\text{F} \times \text{day} \times 0.78}$$

$$\begin{aligned} SHL &= \text{ft} \times \text{hr} \times \text{day} \times 65 - 9 \times \text{yr} \\ &= 61,861 \text{ Btu/ft}^2/\text{yr} \end{aligned}$$

An expression can be developed from the Klamath Falls peak load to determine the peak commercial load for any other area based upon the commercial outside design temperature, T_c . This relationship is:

$$PHL = 33 - 0.508 T_c \text{ (in Btu/hr/ft}^2\text{)}$$

Thus, the annual heating load relationship is expressed as follows:

$$SHL = \frac{(33.0 - 0.508 T_c) \times 24 \times DD \times C_{DC}}{65 - T}$$

(in Btu/ft²/hr)

Using data from the Bonneville Power Administration again, the 1980 commercial penetration or capture rate for electricity is estimated to be 25% of the space heating and 35% of the water heating.

In the United States the Urban Land Institute estimates that commercial land use requirements are between 0.75 and 1.0 acre per 1,000 persons. The heated space in a typical commercial project is calculated as follows:

$$1.00 \times 0.80 \times 0.80 = 0.65 \text{ acres/1,000 population } < 4,000;$$
$$0.75 \times 0.80 \times 0.80 = 0.50 \text{ acres/1,000 population } > 4,000;$$

or $28.31 \text{ ft}^2/\text{person}$ and $21.78 \text{ ft}^2/\text{person}$ respectively.

The commercial water heating load calculations are based upon the following assumptions:

$$\begin{aligned} & 2 \text{ gals/employee/day}, \\ & 2 \text{ employees/1,000 ft}^2, \\ & = 4 \text{ gals/1,000 ft}^2/\text{day}. \end{aligned}$$

Compared to the known residential use of:

$$4,068 \text{ kwhr/yr/residence},$$
$$30 \times 2.8 = .84 \text{ gals/residence/day.}$$

Commercial water heating:

$$= \frac{4,068 \text{ kwhr} \times \text{res} \times \text{day} \times \text{gals}}{\text{yr} \times \text{res} \times 84 \text{ gals} \times 1,000 \text{ ft}^2 \times \text{day}}$$
$$= 0.1937 \text{ kwhr/ft}^2/\text{yr}$$
$$= 661 \text{ Btu/ft}^2/\text{yr}$$

Thus, the following commercial heating load can be estimated for a hydrothermal site:

1. Electric space heating load (saturation rate of 25 percent):

$$\text{SHL}_3 = 0.25 \times \frac{(33.0 - 0.508 \times T_c)}{65 - T_c} \times 24 \times P \times A \times DD \times C_{DC}$$
$$= \frac{(198 - 3.05 \times T_c)}{65 - T_c} \times P \times A \times DD \times C_{DC} \text{ (in Btu/yr)}$$

where:

P = population of the area,

A = 28.31 for $P < 4,000$,

= 21.78 for $P > 4,000$.

DD = degree days of heating,

T_c = commercial outside design temperature, and

C_{DC} = commercial correction factor for outside design temperature.

2. Fossil fuel space heating load:

$$\text{SHL}_4 = 3.00 \times \text{SHL}_3$$

3. Electric water heating load (saturation rate of 35 percent):

$$\begin{aligned} \text{WHL}_3 &= 0.35 \times 661 \times P \times A \\ &= 231.4 \times P \times A \text{ (in Btu/yr)} \\ &= 0.0678 \times P \times A \text{ (in kwhr/yr)} \end{aligned}$$

4. Fossil fuel water heating load:

$$\text{WHL}_4 = 1.857 \times \text{WHL}_3$$

Commercial Summary:

Total space heating load:

$$\text{SHL}_C = \text{SHL}_3 + \text{SHL}_4$$

Total water heating load:

$$\text{WHL}_C = \text{WHL}_3 + \text{WHL}_4$$

Total commercial heating load:

$$\text{CHL} = \text{SHL}_C + \text{WHL}_C$$

In addition, public facility and institutional loads were estimated and combined with commercial loads shown in Part III. The public/institutional uses includes government buildings, schools, churches, and fraternal organizations. Based upon the Klamath Falls experience, the following per capita estimates were made for a typical community's public needs:

Public buildings	3 ft ² /person
Schools	22 ft ² /person
Churches and fraternal	<u>5 ft²/person</u>
Total -	30 ft ² /person

Using the Klamath Falls' commercial heating rate of 28.4 Btu/ft²/hr peak load:

$$30 \times 33 = 990 \text{ Btu/person/hr}$$

The annual rate for Klamath Falls would be:

$$\frac{852 \times 24 \times 6,516 \times 0.78}{65 - 9} = 1.856 \times 10^6 \text{ Btu/person/yr}$$

The peak heating load expression for the public and institutional load for any other area based upon the commercial outside design temperature, T_c , would be:

$$\begin{aligned} PHL &= 30 (33 - 0.508 T_c) \\ &= 990 - 15.2 T_c \text{ (in Btu/person/hr)} \end{aligned}$$

Therefore, the annual public/institutional heating load relationship is expressed as follows:

$$SHL = \frac{(990 - 15.2 \times T_c) \times 24 \times DD \times C_{DC}}{65 - T_c}$$

(in Btu/person/yr).

The corresponding water heating rate based on the commercial usage of $661 \text{ Btu/ft}^2/\text{yr}$ would be:

$$661 \times 30 = 0.0198 \times 10^6 \text{ Btu/person/yr}$$

Thus, the public/institutional heating load for a hydrothermal site can be calculated as follows:

1. Electric space heating load (using the commercial saturation rate of 25 percent):

$$SHL_5 = 0.25 \times \frac{(990 - 15.2 \times T_c)}{65 - T_c} \times 24 \times P \times DD \times C_{DC}$$

$$= \frac{(5,940 - 91.2 \times T_c)}{65 - T_c} \times P \times DD \times C_{DC} \text{ (in Btu/hr)}$$

$$= \frac{(1.74 - 0.0267 \times T_c)}{65 - T_c} \times P \times DD \times C_{DC} \text{ (in kwhr/hr)}$$

2. Fossil fuel space heating load:

$$SHL_6 = 3.00 \times SHL_5$$

3. Electric water heating load (using the commercial saturation rate of 35 percent):

$$WHL_5 = 0.35 \times 0.0198 \times 10^6 \times P$$

$$= 6.930 \times 10^3 \times P \text{ (in Btu/yr)}$$

$$= 20.30 \times P \text{ (in kwhr/yr)}$$

4. Fossil fuel water heating load:

$$WHL_6 = 1.857 \times WHL_5$$

Public/Institutional Summary:

Total space heating load:

$$SHL_p = SHL_5 + SHL_6$$

Total water heating load:

$$WHL_p = WHL_5 + WHL_6$$

Total public and institutional heating load:

$$PHL = SHL_p + WHL_p$$

C. CONSTRAINTS

Finally, it should be noted that a major constraint for this report was a mandatory period of performance of three weeks, from notice to proceed to report distribution. This time constraint precluded a more exhaustive site search through individual state energy agencies; nor have these agencies had an opportunity to review and comment upon results as reported herein. It has been this time constraint and the inability for individual state-level coordination which necessitates the "preliminary" nature of this report.

III. INVENTORY OF CITIES

ALASKA

City	Current Population ¹	Growth Rate(%) ²	No. of Sites	Resource Data ³		Estimated Community Heating Load (x10 ⁹ BTU/yr.)		
				Temp. Range(F.)	Depth Range(Ft.)	Residential	Commercial	Total
