ABSTRACT

The High Cascades volcanic province has long been suspected to contain considerable geothermal potential. However, few deep wells have been drilled, and much of the data that have been accumulated are proprietary. In response to the need to obtain a better understanding of the Cascades region, the U.S. Department of Energy, Geothermal Technology Division, sponsored a cooperative research program with industry based around obtaining data from research coreholes. This paper is a progress report on the three coreholes completed to date, including a summary of drilling histories and a description of the scientific studies underway and of the open file data available.

INTRODUCTION

The Cascades is an area with high hydrothermal potential, but with few surface manifestations. The lack of widespread surface hydrothermal activity is generally believed to result from the masking of systems by downward and lateral movement of cold, meteoric water. In 1986, the U.S. Department of Energy, Geothermal Technology Division, initiated the Caldera Reservoir Investigation Program to evaluate the effects of the near-surface hydrologic regime and to obtain lithologic, hydrologic, and structural data on the Cascades.

The DOE program has four main elements: 1) cost sharing with industry in coring research holes; 2) acquisition of lithologic, geophysical, and hydrologic data within and below the shallow hydrologic regime; 3) data interpretation and integration; and, 4) open file release of data and core, as well as publication of technical reports and case histories.

Summaries of drilling histories and descriptions of the available data and scientific studies are presented in this paper for three holes drilled under the DOE program: Clackamas Thermal Gradient Hole #1 (CTGH-1), drilled by Thermal Power Co.; and GeoNewberry holes # 1 and # 3 (GEO N-1 and GEO N-3), drilled by GEO Operator Corporation. CTGH-1 is located approximately 10 miles north of Mt. Jefferson, while GEO N-1 and GEO N-3 are located on the southern and northern flanks, respectively, of the Newberry volcano. Figure 1 shows the locations of these holes.

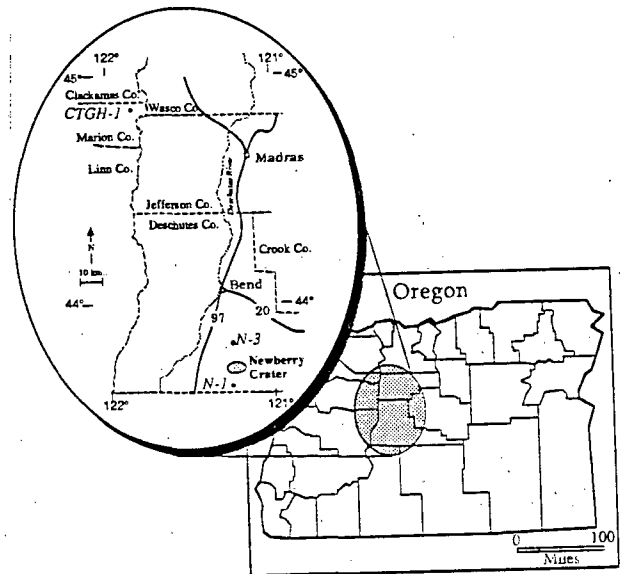

Figure 1. Location map of core holes.

CORING SUMMARY

CTGH-1

CTGH-1 was rotary drilled to a depth of 527 feet, and then diamond cored to a total depth of 4,800 feet. The hole

required 93 days to complete; however, only 58 days were spent drilling. CTGH-1 has not been plugged and abandoned at this point. The hole condition is believed to be good so that deepening may be possible.

There were several unanticipated delays during the drilling of CTGH-1. First, the attempt to run a conductor into the top 40 feet of glacial boulders and till was not initially successful. Later, during the change-over from rotary drilling to wireline coring, there were problems setting the casing to the bottom of the hole. In addition, the initial test of the BOP detected a leak, requiring a new flange. Another significant delay occurred during coring at a depth of 4,203 feet, when the HX rods parted at 823 feet. After unsuccessful attempts at retrieval, coring was continued with NX rods, and the HX rods were left in the hole as casing. This precluded the collection of a full suite of geophysical logs, since some logs can not be run in a cased hole. Finally, at a depth of 4,800 feet, the U.S. Forest Service shut down rig operations because of a Class E fire risk. The results of a temperature survey run nine days after the shutdown, in which the bottom-hole temperature was found to be 99°C (210°F), led to a decision not to continue drilling.

GEO N-1

GEO N-1 was rotary drilled to a depth of 487 feet, and then diamond cored to a total depth of 4,550 feet (Swanberg and Combs, 1986). Data and core obtained to a depth of 4,000 feet are in the public domain. Drilling progressed smoothly; out of the 59 days required to reach a depth of 4,000 feet, 54 days were spent drilling. GEO N-1 has been scheduled to be plugged and permanently abandoned before September of 1988.

There were only a few minor problems in the drilling of GEO N-1. During rotary drilling, the rods parted, leaving the rods, sub and bit in the hole, and requiring removal with a tap. An additional delay occurred during the change-over from rotary drilling to wireline coring, when leaks were detected in the BOP.

GEO N-3

GEO N-3 was rotary drilled to a depth of 454 feet and then diamond cored to the total depth of 4,002 feet. Of the 60 days on site, 46 were spent drilling. GEO N-3 is scheduled to be plugged and abandoned before September, 1988.

There were several technical problems encountered in the drilling of GEO N-3. During the change-over from rotary drilling to wireline coring, the initial attempts at cementing the casing were not successful. In addition, the BOP tested negative due to faulty equipment. One significant problem the other two holes did not have was consistent caving in the cinder/ash units. This was particularly a problem when pulling out of the hole to change bits. In one instance, the caving caused the HQ rods to stick. After futile attempts at retrieval, as well as a loss of 138 feet of previously drilled hole, the HQ rods were cemented in place and the hole was reentered with NQ rods. Once again, this limited geophysical logging.

Comparison of Drilling Histories

Depth penetration profiles are shown in Figure 2 for the three holes. The overall daily penetration rate for CTGH-1 was 88 feet/day. For GEO N-1, the overall daily penetration rate to 4,000 feet was 69 feet/day. Finally, for GEO N-3, the overall penetration rate was 68 feet/day. According to Thermal Power Co. (1987), no systematic relationship between penetration rate, rock type and/or degree of fracturing was discerned. This seems to apply to the Newberry volcano holes as well.

Core recovery was excellent in CTGH-1 and GEO N-1, averaging nearly 100%. In GEO N-3, core recovery was equally good in the basaltic-andesite flows. However, GEO N-3 had several thick sections of cinders and ash where core recovery was significantly lower. During rotary drilling of the upper portions of the hole, cuttings were collected only in CTGH-1. There was continual loss of circulation during rotary drilling of the Newberry holes, with no returns.

A detailed itemization of project expenditures for CTGH-1 is given in Table 1a. Approximate expenditures for GEO N-1 and GEO N-3 are given in Table 1b. The overall unit cost for CTGH-1 was \$95/foot; for GEO N-1 the overall cost was \$72/foot (not including logging and demobilization); and for GEO N-3 the cost was \$90/foot.

DATA ACQUISITION AND AVAILABILITY

A significant amount of data has been obtained on the lithologies, temperature gradients, and hydrologic regimes of the areas penetrated by the coreholes. Simplified lithologic columns for CTGH-1, GEO N-1 and GEO N-3 are given in Figure 3. For more detailed information, refer

Figure 2. Depth penetration profile for CTGH-1, GEO N-1, and GEO N-3. Information based on daily drilling reports in open file data.

to the open file reports. In general, the lithologies are similar, consisting of basalt/basaltic-andesite flows. All of the holes have interbedded pyroclastic and volcanoclastic units. In GEO N-3, these units are thicker than in the other holes, and since they are poorly consolidated as well, caving occurred during

Figure 3. Generalized lithologic columns and temperature-depth profiles for CTGH-1, GEO N-1, and GEO N-3. Temperature-depth curves based on Blackwell and Steele (1987); MRT data, shown by "x"s, from open file reports. CTGH-1 and GEO N-1 lithologic columns modified from Sibbett, unpublished data.

the drilling of GEO N-3 that was not present in GEO N-1 and CTGH-1.

Figure 3 also compares the temperatures measured by Blackwell and Steele (1987) with those recorded using a maximum recording thermometer (MRT) during drilling. The temperature profiles for GEO N-1 and GEO N-3, after allowing the wells to stabilize, appear to reflect intra-hole fluid flow (Blackwell and Steele, 1987). In GEO N-3, they suggest that the temperature distribution results from upward movement of water in the wellbore. Similarly, the thermal profile of GEO N-1 could be produced by downward flow of water within the wellbore.

Since temperatures measured during drilling may be recorded before any significant intra-hole fluid flow has begun, MRT data should provide an indication of the depth to the base of the cold-water hydrologic regime. Figure 3 shows that the MRT temperatures are nearly constant with depth in the upper portions of all three holes. Below this zone, the

gradients increase and higher temperature are recorded. We suggest, based on these measurements, that the lower boundary of the cold water regime is located at depths of about 3,600 feet in GEO N-1, 3,000 feet in GEO N-3, and about 1,600 feet in CTGH-1.

Comparison of the thermal profiles with the lithologic logs demonstrates that fluid movement may be influenced by rock type. For example, in GEO N-3, flow out of the wellbore occurs around 1,800 to 1,900 feet in an unconsolidated cinder and ash unit. The water appears to enter this well in interbedded pyroclastics and basalts. Additional information on GEO N-1 and GEO N-3 is given by Blackwell and Steele (1987). GEO N-1 has also been summarized by Swanberg and Combs (1986).

Geophysical well logs were run in all three holes shortly after hole completion. In both CTGH-1 and GEO N-3, it was not possible to obtain complete logs due to the casing. Table 2 lists the logs available, and the corresponding depth intervals.

Analysis of the well logs is presently being conducted. There are several other scientific studies underway on the three coreholes. Table 3 lists these studies as well as the entities that are conducting the studies. In addition, an attempt will be made to obtain a fluid sample from GEO N-3 before the hole is plugged and abandoned.

A summary of open-file data is given in Table 4. Core from the three holes is also available for inspection at the University of Utah Research Institute sample library by appointment.

An additional core hole has been drilled along the east side of Crater Lake National Park, Oregon by California Energy as part of the DOE/Industry cost-share program (located south of area shown in Figure 1). The hole has been

drilled to approximately 1,400 feet, with a temperature at TD of 107°C (225°F) (Blackwell and Steele, 1987). However, drilling has been halted while possible effects of geothermal development on Crater Lake are evaluated. Some of the issues surrounding this evaluation are discussed by La Fleur (1987) and Sammel and Benson (1987). If continued drilling is approved studies and data, similar to that acquired on the other holes drilled under the DOE cost-share program, will become available for the Crater Lake hole.

SUMMARY.

As part of a DOE-industry cooperative research program, three deep holes were cored in the Cascades to depths of 4,000 to 5,000 feet. The main objective of the program was to penetrate the near-surface

hydrologic regime and obtain lithologic, hydrologic and structural data on the Cascades that would be available to the public. The near-surface hydrologic regime was penetrated by all three holes, and the appropriate data collected. At the present, studies on these three holes are still underway.
