1.0.0 INTRODUCTION

In July and October, 1979, MicroGeophysics Corporation performed a gravity survey in and around the McCoy Peak area, Nevada (Figure 1.1). The gravity survey of 1 square mile station density has elevation controls, USGS benchmarks, topographic elevations, and where neither existed, vertical control was achieved by barometric altimetry.

Gravity surveys are of particular importance when used as a tool to distinguish structure. The McCoy survey area is an area of complex structural geology. The data collected near McCoy indicates that the graben containing the Edwards Creek basin is considerably larger than its surface manifestations. In addition to the extended valley structure obtained from the data, a location of a north trending fault on the eastern boundary of the survey was established and a location of a northwest trending system on the northern area boundary was outlined.

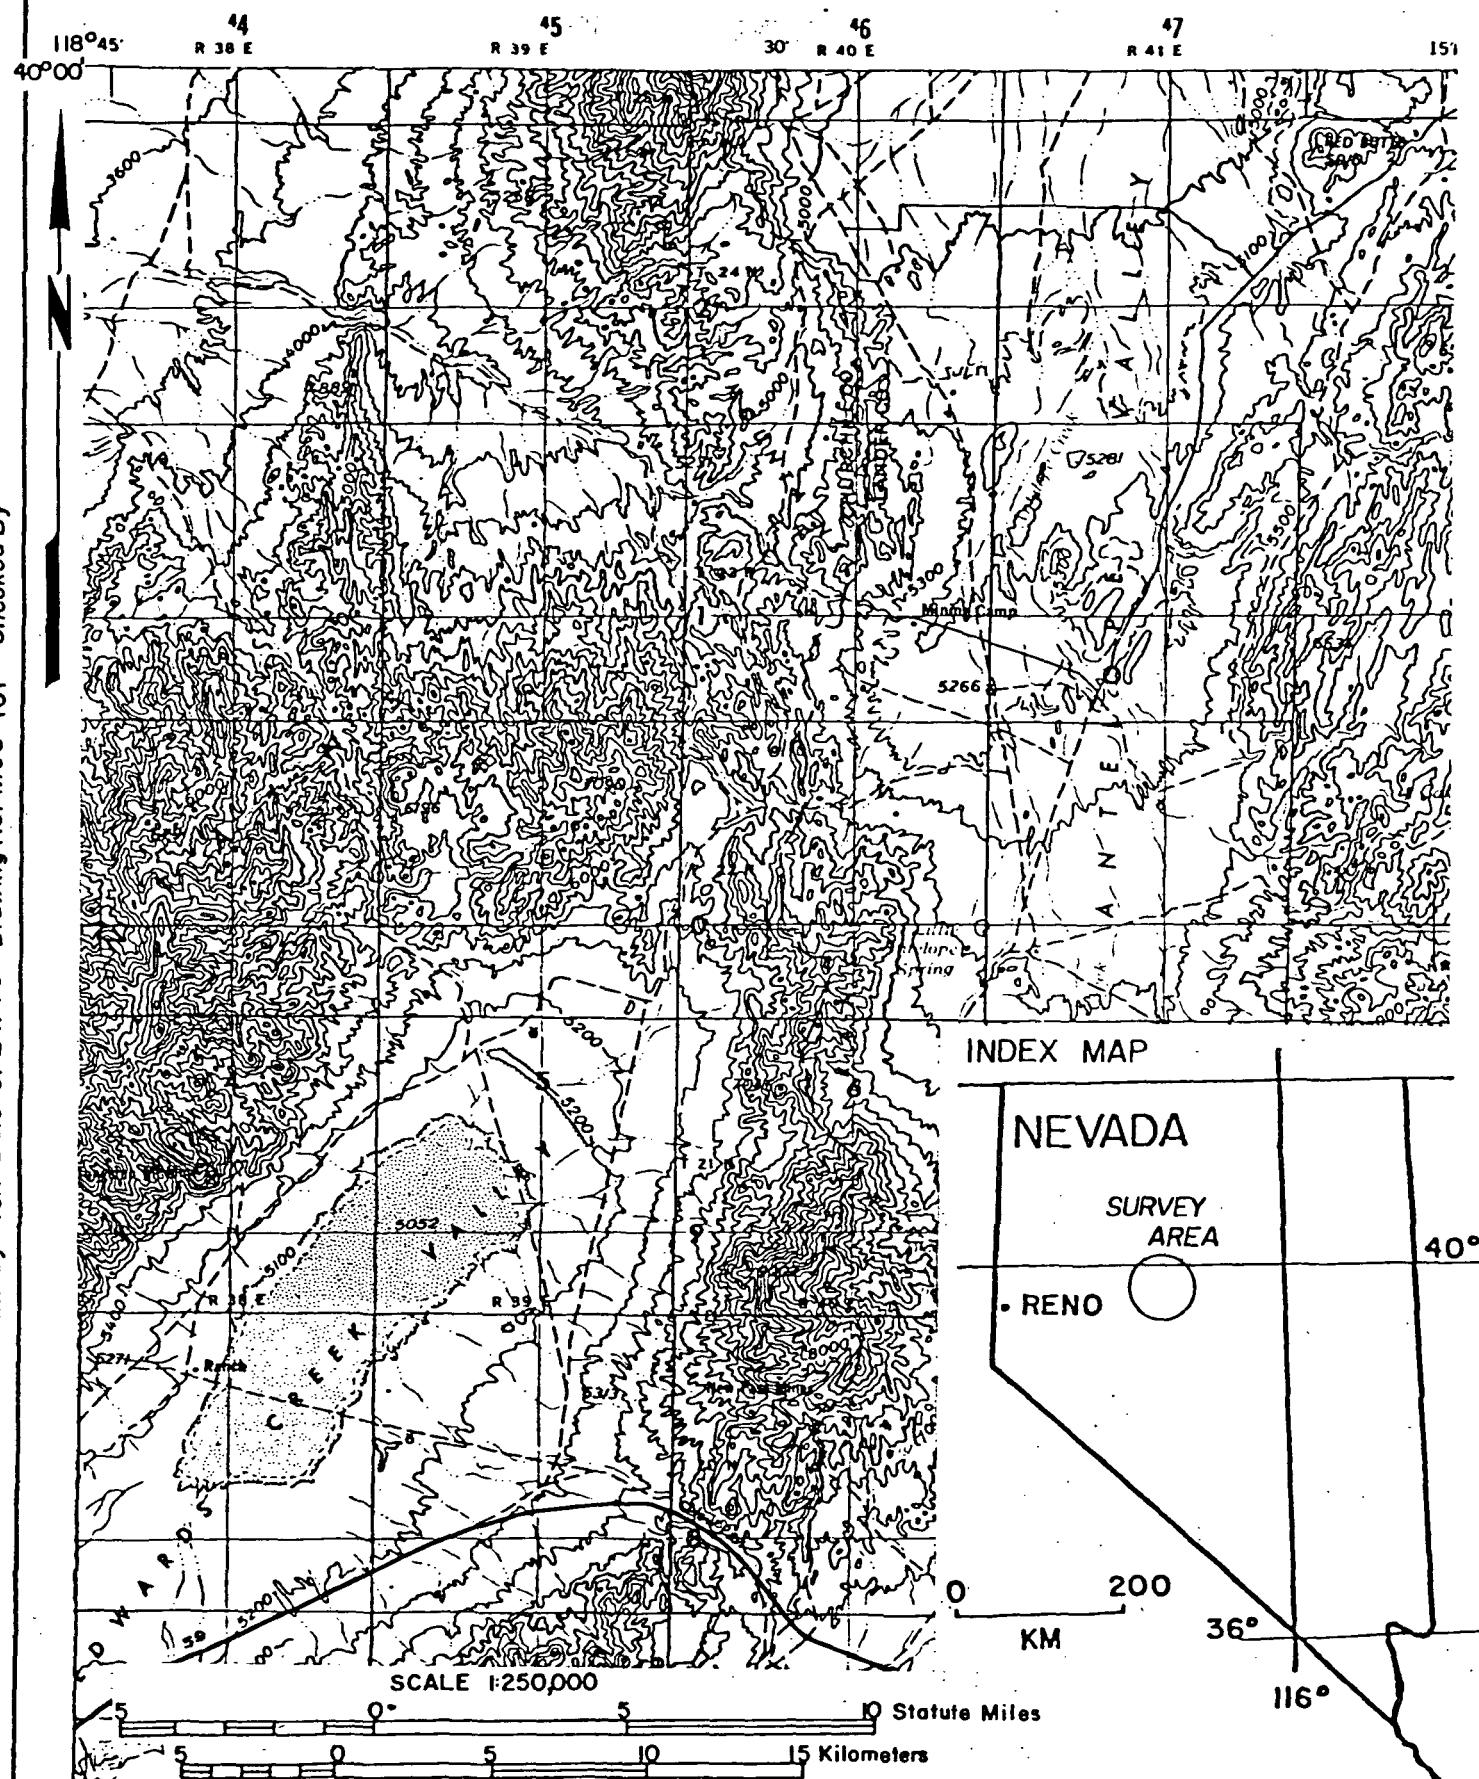

2.0.0 FIELD PROCEDURE AND INSTRUMENTATION

2.1.0 Gravity

MicroGeophysics Corporation (MGC) began work on the McCoy, Nevada gravity project on June 25, 1979. Data was collected by MGC to add to that gravity data previously collected by AMAX geophysicists.

Gravity measurements were made using LaCoste and Romberg model G gravity meters numbers 473 (June-July), 370 (Oct.), and the

LOCATION AND INDEX MAP

AMAX gravimeter number 345. Upon preliminary processing of the combined MGC (from June-July) and AMAX data sets, several low station density areas were outlined for additional gravity coverage. In addition to these low station density areas, two anomalies with unreasonably high gradients were discovered. These two anomalies were N-S trending with one superimposed upon the Clan Alpine Range just south of "Hole in the Wall". The second parallel the first four miles to the east. Stations occupied highlighting both of these anomalies were confined to a single line each. The terrain along these lines was such as to require backpacking of the instrument. Temperatures in the area on both days were 100°+F. We have postulated that for both lines the temperature within the case exceeded 48.3°C (119°F) operating temperature of the instrument, thereby causing it to become unstable. In the course of a gravity survey where base ties are frequent throughout the day, such errors are easily uncovered. However, on this network base ties were completed only early in the morning and after dark on the way to the base camp. With the time needed to hike out of an area and return to base the instrument probably cooled to its operating temperature thereby eliminating any evidence of instability during the day. Therefore in October 1979, a field crew returned to the McCoy area to increase the station density in the sparsely covered areas and to repeat the measurement points where the instrument had been unstable.

2.2.0 Altimetry

Barometric leveling was used in the McCoy area by MGC only during the October 1979 field work. Throughout the rest of the work, spot elevations and benchmarks provided the vertical control.

Several precautions were incorporated in the altimetry to insure accurate elevation determinations. A micro-baragraph was used to record changes in barometric pressure at the base for each loop. This base was always selected as close as possible spatially and vertically to the area to be surveyed. In addition both the altimeter and micro-baragraph were kept in coolers with the temperature controlled by the use of "Blue Ice". This was to eliminate drift due to incorrect thermal compensation.

3.0.0 INTERPRETATION

The free-air and Bouguer anomalies (Table 3.1) were calculated using the Geodetic Reference System, 1967. Exact determination of the Bouguer density was not made in this area. An assumed value of 2.67 g/cc was used for this survey area. Table 3.1 lists the observed and theoretical gravity, free-air, and Bouguer anomalies (simple), latitude, longitude and elevation for each station. Table 3.2 lists the simple Bouguer anomaly, terrain correction for the Hammer Zones D-M and the complete Bouguer anomaly. These values were used to generate the complete Bouguer anomaly map (Plate 2).

In both Plates 1 & 2 single point values that did not fit well with the near-by data trend were discarded in the final contour maps. As seen on both plates, the gravitational field changes a great deal (45^+ mgals) across the survey area. A contour interval of 5 mgals was therefore chosen in order to thoroughly outline gravitational trends without isolating too many single point anomalies.

Several major structural trends are seen on Plate 2. The first trend is an apparent northward extension of the gravitational low associated in the Edwards Creek basin. This low is bounded on the west and east-northeast by two major north-south lineations.

4.0.0 CONCLUSIONS AND RECOMMENDATIONS

The gravity method as employed near McCoy, Nevada produced very good results as to the structure of the Edwards Creek basin and its northern continuation. Any of the faults outlined are primary control to fluid flow in the area. Any further work in the McCoy area should be primarily centered around the faulted regions to the north and east of the project area. Of course, the gravity results should be used to limit or highlight the structural interpretation in the area.
