ABSTRACT

The McCoy geothermal prospect is located at the junction of the Augusta Mountains, Clan Alpine Mountains and the New Pass Range. The prospect was discovered in 1977 and in 1978 was made a part of the Geothermal Reservoir Assessment Case Study Program of the Department of Energy under contract DE-AC 08-79 ET 27010.

Geothermal exploration done during 1980 included geological and geochemical studies. Geophysical work included interpretation of gravity data, a tensor MT survey and an EM-60 survey by the Lawrence Berkley Laboratory. Two intermediate depth exploration wells were completed in 1980.

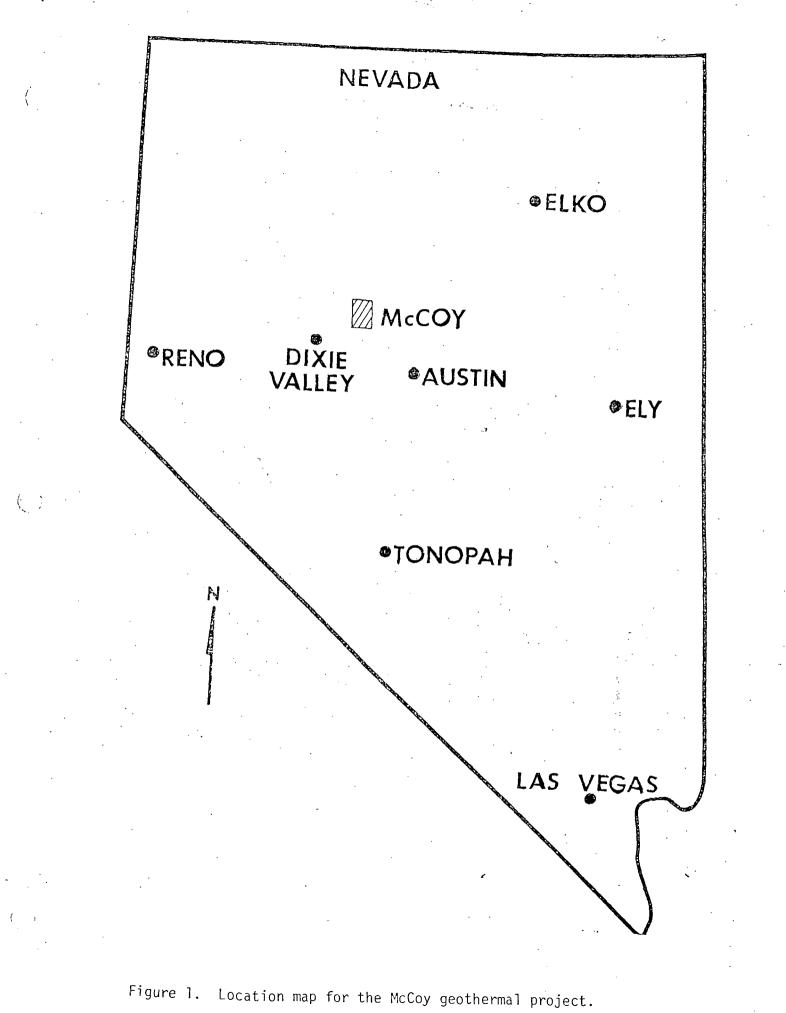

A shallow low-temperature geothermal reservoir was encountered in the Triassic rocks. The analysis of the exploration continued in an attempt to determine the source area for the thermal fluids.

INTRODUCTION

The McCoy geothermal prospect was discovered in 1977 during reconnaissance coverage of Nevada. The prospect was identified by thermal gradient measurements of existing holes and hydrogeochemical analysis of well water from the McCoy Mine water well. The prospect is located approximately 72 kilometers northwest of Austin, Nevada (Figure 1) and can be reached by means of a graded road which leads from U. S. Highway 50.

The McCoy prospect is located at the confluence of the Augusta and Clan Alpine Mountains and the New Pass Range. The prospect straddles the Churchill and Lander County borders.

In 1978 AMAX submitted a proposal in response to the Department of Energy's RFP No. ET-78-R-08-003, Geothermal Reservoir Assessment Case Study, Northern Basin and Range and was awarded a contract providing partial funding for exploration at the property. Detailed results of the work funded through the DOE will be published by the DOE through the University of Utah Research Institute (UURI) under DOE contract DE-AC 08-79 ET 27010.

- 3 -

EXPLORATION HISTORY

The geothermal exploration partially funded under DOE contract DE ACO8-79 ET 27010 was an integrated approach including geological, geochemical and geophysical studies as well as exploration drilling. For the purpose of this report the exploration will be discussed under exploration methods rather than a chronological description.

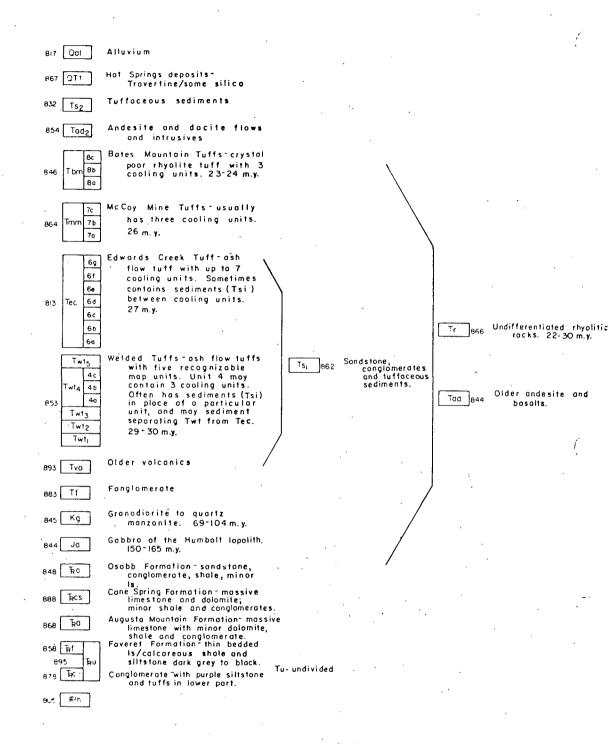

GEOLOGICAL STUDIES

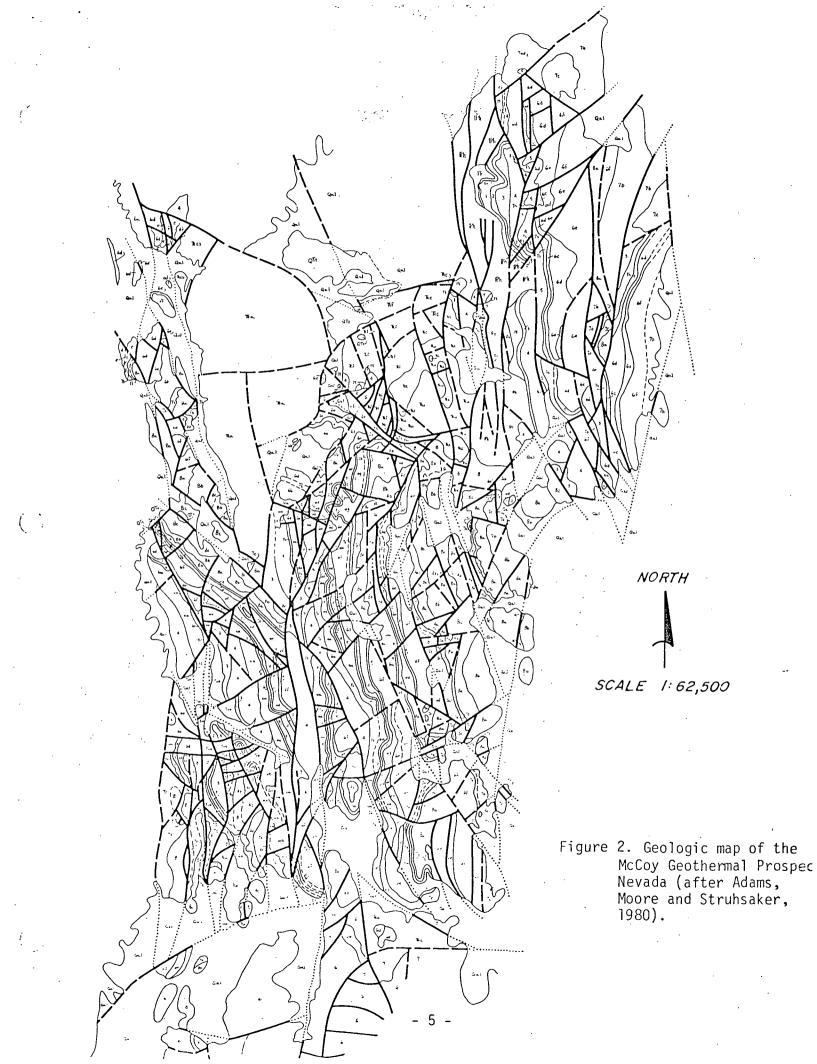

The McCoy geothermal prospect is located at the junction of the Augusta Mountains, the Clan Alpine Mountains and the New Pass range. The area is underlain by Tertiary volcanics and associated sediments, Triassic sediments and Permo-Pennsylvanian eugeosynclinal sediments as shown on the county maps (Stewart, J. H. and McKee, E. H., 1977 and Wilden, R. and Speed, R. L., 1974). The county geologic maps are at a scale of 1:250,000 and, therefore, do not show much detail.

In the late fall of 1979 Joe Moore of the University of Utah Research Institute began a geologic mapping program under DOE contract DE-AC 07 - 80 ID 12079. Joe Moore and Eric Struhsacker established the mapping units in the Tertiary volcanics and then Mike Adams of UURI did most of the field mapping in 1980. A detailed geologic map at a scale of 1:24,000 has been completed (Figure 2).

The oldest rocks mapped in the McCoy area are the cherts, volcanics, siltstones, sandstones and minor limestones of the Havallah sequence of Permo-Pennsylvanian age. The rocks were deformed, uplifted and deeply eroded prior to the deposition of the basal Triassic sediments which

- 4 -

consist of conglomerates, siltstones, sandstones and minor tuff. The basal member is overlain by several hundred feet of dominantly carbonate sediments of the Favret Formation, the Augusta Mountain Formation and the Cone Springs Formation. The uppermost Triassic unit is the detrital sediments of the Osobb Formation.

The Tertiary volcanic rocks in the McCoy area (Fig. 2) range in age from about 36 m.y. to 15 m.y. (McKee and Stewart, 1971). Sedimentary rocks are found at various horizons within the volcanic units. A considerable thickness of sediments overlie the volcanic rocks to the northwest of the McCoy Mine area. West of the McCoy Mine over 2km² of fossil Quaternary travertine is exposed. The travertine lies unconformably upon the eroded Triassic rocks. The travertine dips gently westward and is only slightly dissected.

Tectonically the area has had a long and complex history. The detailed mapping permitted the construction of detailed geologic cross section (Fig. 3). Reasonable approximations of the fault offsets could be made using the displacement of cooling units on Mike Adams geologic map.

Geochemical Studies

The hydrogeochemical analysis of a water sample from the McCoy Mine water well was one of the manifestations which attracted AMAX to the McCoy area. During the exploration drilling in 1980 water was encountered in well 66-8. Table I compares the chemical analyses from McCoy Mine well and exploration well 66-8.

- 9 -

Chemically the waters from Well 66-8 and the McCoy Mine well are sodium bicarbonate waters with projected subsurface temperatures of $98-148^{\circ}$ C based upon the conductive quartz geothermometer and $153^{\circ}-206^{\circ}$ using the N-K-Ca geothermometer.

5.54 3. 1

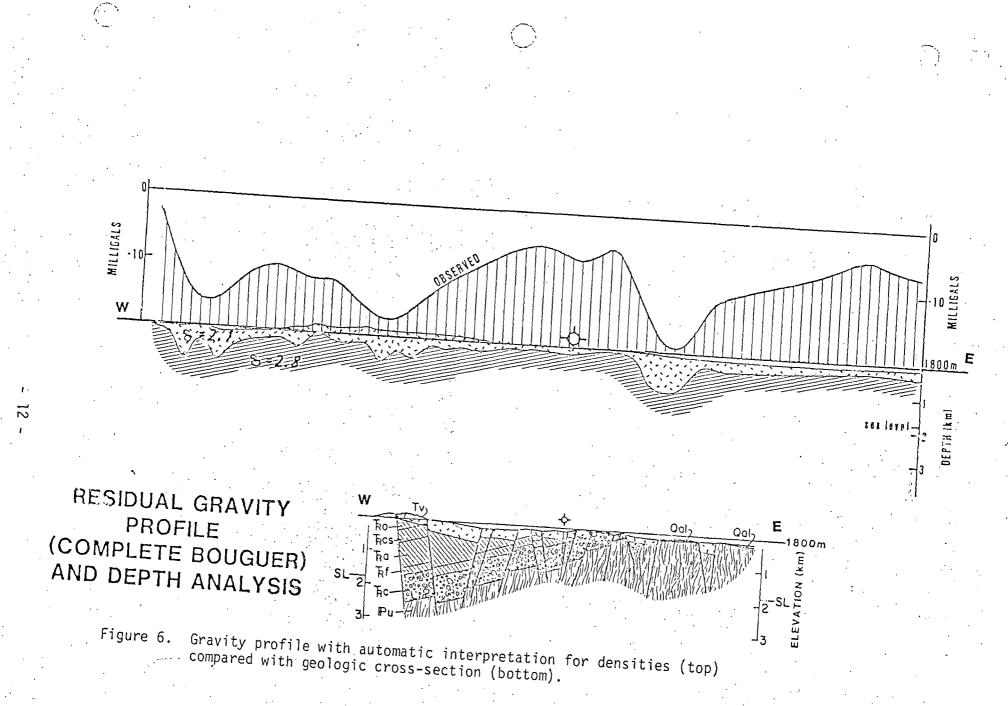

In 1979 Joe Moore of the University of Utah Research Institute proposed to undertake a geochemical study of the drill cuttings from McCoy. AMAX agreed to provide Joe with a split of our samples. UURI prepared composite samples for the intervals of 0-40, 40-80, 80-120 and 120-160 feet for each shallow thermal gradient hole (Figure 4). The geochemical study was done under DOE contract DE-AC 07-80 ID 12079. Multielement geochemical analyses using Inductively Coupled Plasma-Atomic Emission Spectroscopy (Moore 1980) were performed on each composite sample. Preliminary analysis of the data from Joe Moore indicates that Zn, As, Pb, F and Hg show some correlation with the thermal anomaly and also with the known areas of hydrothermal alteration and mineralization. Figure 5 shows the contour map for mercury for the interval 120-160 feet. The contour pattern appears to emphasize certain structural directions and the linear trends become more pronounced with depth (Pilkington, 1980).

Geophysical Studies

A gravity survey of 340 stations was conducted by AMAX and Microgeophysics in 1979 and Fred Berkman has been involved in the analysis of the data. Berkman prepared a residual gravity profile (Complete Bouguer) and depth analysis along an east-west line through well 66-8 (Figure 6) as reported by Lange, 1980. The gravity interpretation (top) is compared with the geologic cross-section by Pilkington (1980) on the bottom part of Figure 6.

- 10 -

A tensor MT survey was run by Terraphysics in February 1980 (Lange, 1980) at the McCoy property (Fig. 7). The location of the lines along which the MT survey was done are shown on Figure 7. The resistivity as deduced by Lange (1980) at a depth of 5 km from the ID inversion of the MT (Te mode) is also shown on Figure 7. The MT section along line C-C' (Figure 8) illustrates the correlation with geology. Lange (1980) believes the MT sees a deep reservoir, (three or more kilometers) along line C-C' which is leaking fluids up the faults bounding the horst block east of well 66-8.

As a part of the Department of Energy's program to stimulate the development of geothermal resources Lawrence Berkley Laboratory (LBL) conducted a survey with the EM-60 frequency domain system over the McCoy prospect (Wilt, M. et al, 1980). The stations for the LBL survey are shown in Figure 9. The survey consisted of 19 frequency-domain electromagnetic soundings from three transmitter loops. A comparison between the EM data from LBL and the AMAX MT data is shown in Figure 10. Wilt et al (1980) conclude that the EM results agree well with the data gathered from well 66-8. A conductor was found at the approximate depths that boiling water was found in the well. The EM does give information on the shallow depths where MT does not give reliable results.

Exploration Drilling

Two intermediate depth exploration wells were completed in 1980. Well 66-8 located in the NWSE Sec. 8 T22N R40E had a TD of 765 meters (2510') and well 14-7 located in the SE NW Sec. 7 T23N R40E had a TD of 613m (2010').

GEOLOGIC PROFILE

Figure 8. MT section (T mode, 1D inversion) along Line C, compared with geologic section - 15 -

. .

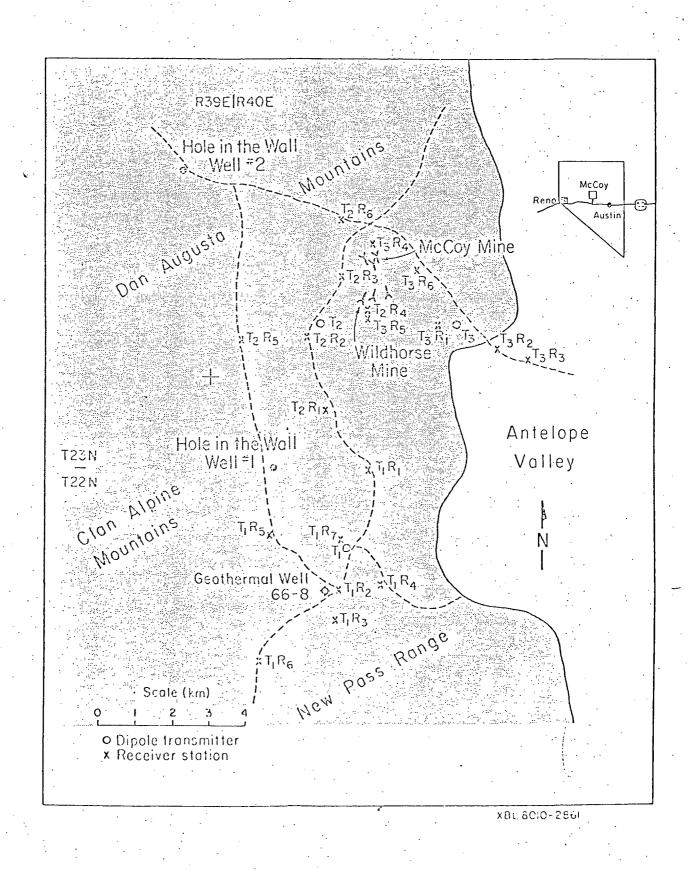

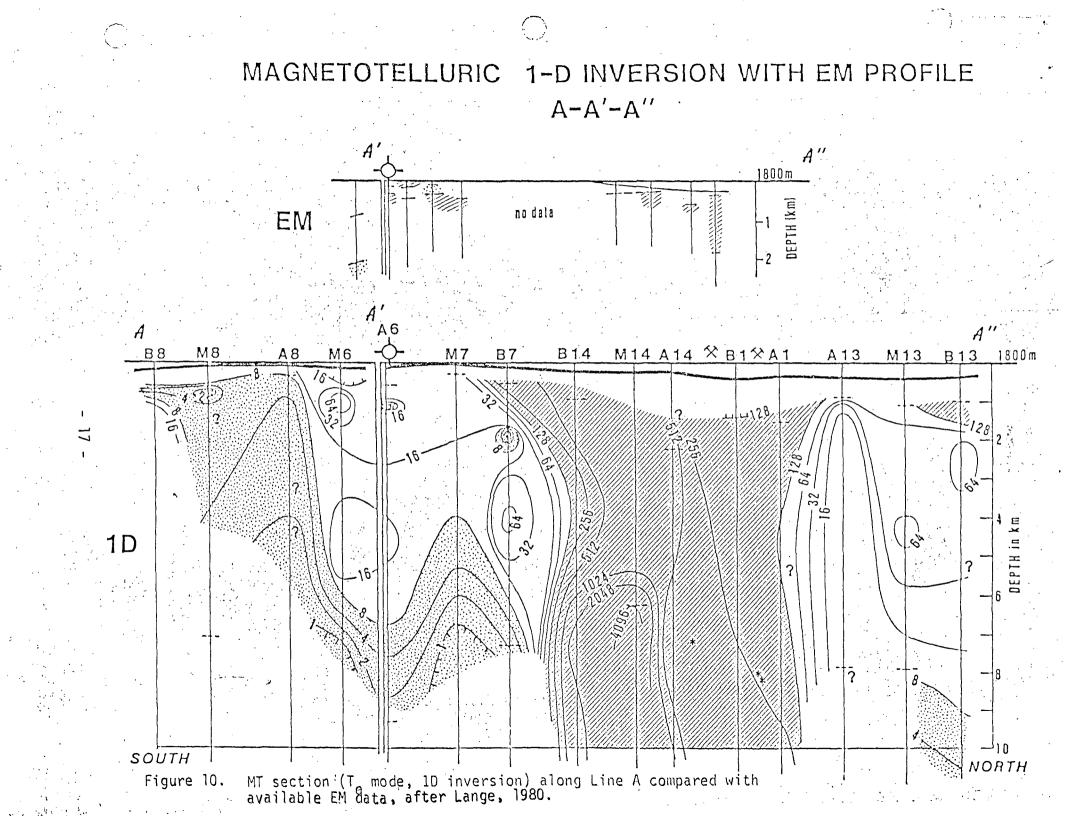

Figure 9. Survey location map of the McCoy prospect. after Wilt et al, 1980.

Both wells were drilled as unit wells for the McCoy Federal Geothermal Unit under a Plan of Operation approved by the U.S. Geological Survey. The generalized drilling plan for the holes was:

1. Move on. Rig up.

2. Drill 17-1/2" hole to +20 ft.

3. Run 20 ft of 13-3/8 conductor pipe, cement.

4. Drill 12-1/4 hole to +505 ft.

5. Run 500 ft of 8-5/8" casing, cement.

6. Install BOP equipment, test.

7. Drill 6-1/4-6-3/4 hole to TD.

8. Run electric logs.

9. Equip hole for flow test if appropriate

10. Equip hole for temperature observation if no suitable production encountered - 3" Black iron pipe installed capped top & bottom filled/water.

Well 66-8 encountered a low temperature geothermal reservoir between 1630 feet and TD. Numerous hot water entries were recorded; with first entry at 1630 feet being the hottest at about 100^oC, or just slightly above boiling for the elevation. The chemistry of the fluids was discussed in the section on geochemical studies. Lost circulation was encountered at several depths below the upper water zone. After completing the well as a thermal observation well it was discovered that drilling mud left in the hole had flowed out into the formation, and the 100^oC water flows into the hole and out one of the lost circulation zones near bottom of hole. Therefore, no valid temperature gradients can be measured. It is proposed to back fill the annulus in 1981 to try and obtain reliable bottom hole temperature data.

- 18 -

Well 14-7 encounterrd lost circulation in the Triassic carbonates at a depth of 409 feet. With considerable difficulty the 8-5/8" casing was set and cemented at a depth of 495 feet. A flow of warm water $\pm 50^{\circ}$ C was encountered just below the casing. Below 800 feet drill blind with no returns to TD. The well was completed as a temperature observation well, but the $\pm 50^{\circ}$ C water at 500 feet is going out into formation somewhere near the bottom of hole so that hole is isothermal below 500 feet.

ABSTRACT

1. A.A.

The McCoy geothermal prospect is located at the junction of the Augusta Mountains, Clan Alpine Mountains and the New Pass Range. The prospect was discovered in 1977 and in 1978 was made a part of the Geothermal Reservoir Assessment Case Study Program of the Department of Energy under contract DE-AC 08-79 ET 27010.

Geothermal exploration done during 1980 included geological and geochemical studies. Geophysical work included interpretation of gravity data, a tensor MT survey and an EM-60 survey by the Lawrence Berkley Laboratory. Two intermediate depth exploration wells were completed in 1980.

A shallow low-temperature geothermal reservoir was encountered in the Triassic rocks. The analysis of the exploration continued in an attempt to determine the source area for the thermal fluids.

INTRODUCTION

The McCoy geothermal prospect was discovered in 1977 during reconnaissance coverage of Nevada. The prospect was identified by thermal gradient measurements of existing holes and hydrogeochemical analysis of well water from the McCoy Mine water well. The prospect is located approximately 72 kilometers northwest of Austin, Nevada (Figure 1) and can be reached by means of a graded road which leads from U. S. Highway 50.

The McCoy prospect is located at the confluence of the Augusta and Clan Alpine Mountains and the New Pass Range. The prospect straddles the Churchill and Lander County borders.

In 1978 AMAX submitted a proposal in response to the Department of Energy's RFP No. ET-78-R-08-003, Geothermal Reservoir Assessment Case Study, Northern Basin and Range and was awarded a contract providing partial funding for exploration at the property. Detailed results of the work funded through the DOE will be published by the DOE through the University of Utah Research Institute (UURI) under DOE contract DE-AC 08-79 ET 27010.

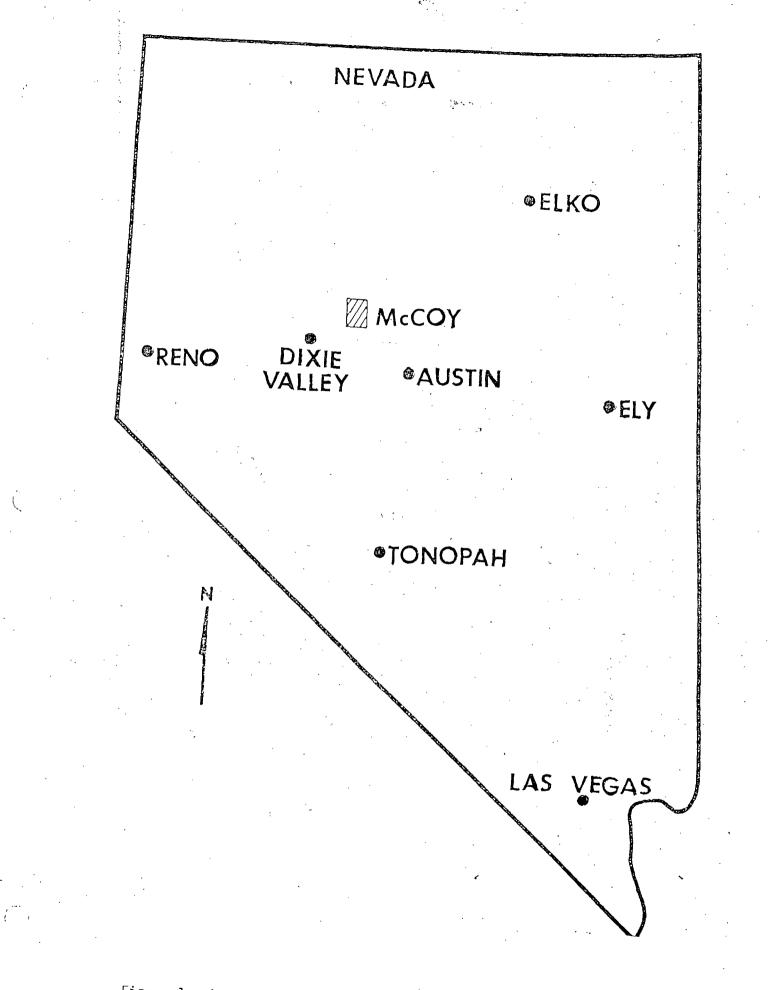

Figure 1. Location map for the McCoy geothermal project.

EXPLORATION HISTORY

The geothermal exploration partially funded under DOE contract DE ACO8-79 ET 27010 was an integrated approach including geological, geochemical and geophysical studies as well as exploration drilling. For the purpose of this report the exploration will be discussed under exploration methods rather than a chronological description.

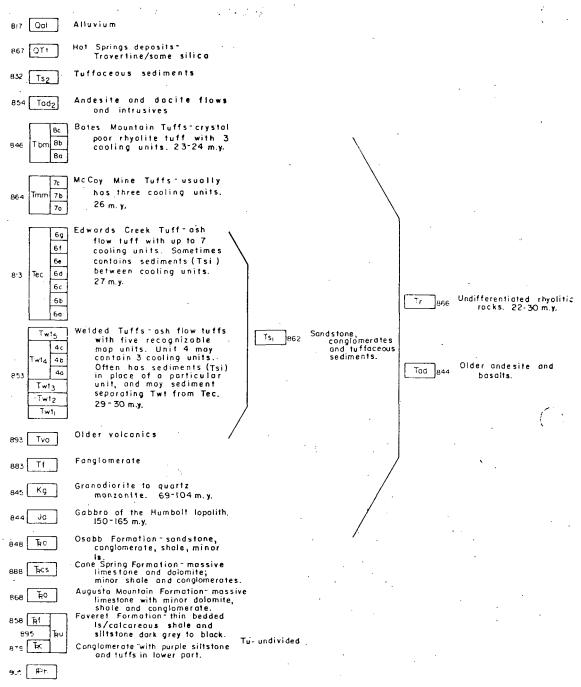

GEOLOGICAL STUDIES

The McCoy geothermal prospect is located at the junction of the Augusta Mountains, the Clan Alpine Mountains and the New Pass range. The area is underlain by Tertiary volcanics and associated sediments, Triassic sediments and Permo-Pennsylvanian eugeosynclinal sediments as shown on the county maps (Stewart, J. H. and McKee, E. H., 1977 and Wilden, R. and Speed, R. L., 1974). The county geologic maps are at a scale of 1:250,000 and, therefore, do not show much detail.

In the late fall of 1979 Joe Moore of the University of Utah Research Institute began a geologic mapping program under DOE contract DE-AC 07 - 80 ID 12079. Joe Moore and Eric Struhsacker established the mapping units in the Tertiary volcanics and then Mike Adams of UURI did most of the field mapping in 1980. A detailed geologic map at a scale of 1:24,000 has been completed (Figure 2).

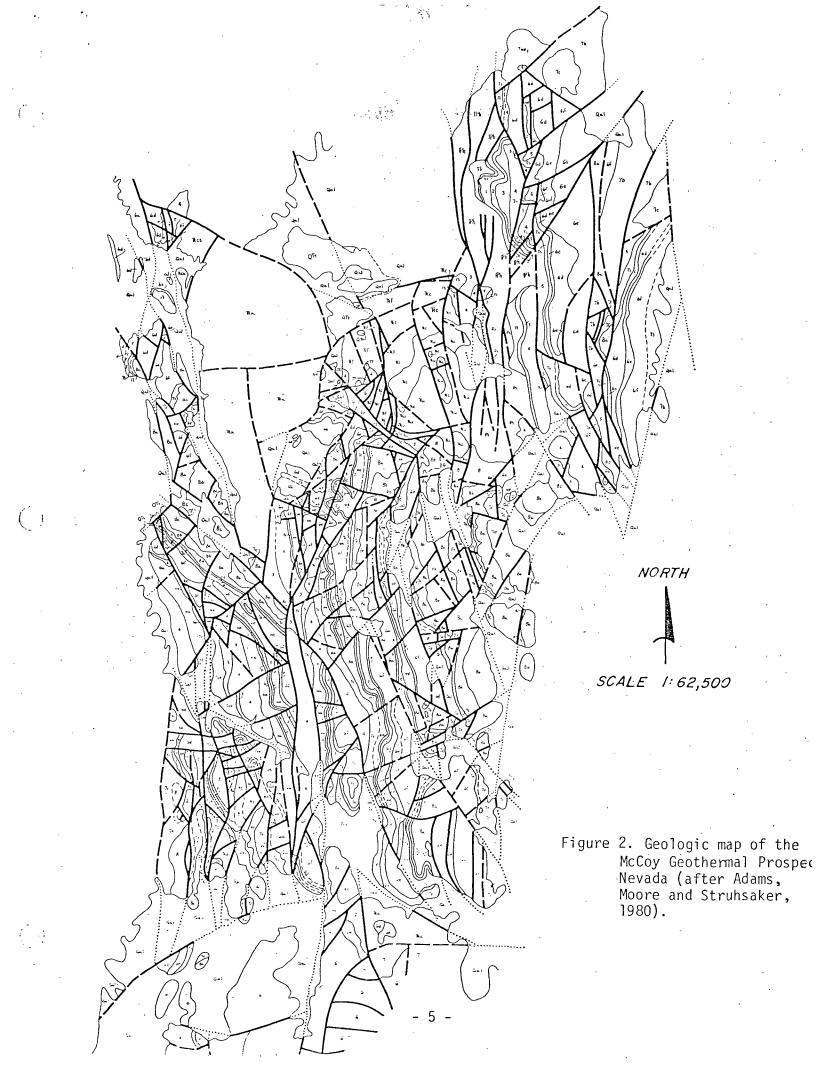

The oldest rocks mapped in the McCoy area are the cherts, volcanics, siltstones, sandstones and minor limestones of the Havallah sequence of Permo-Pennsylvanian age. The rocks were deformed, uplifted and deeply eroded prior to the deposition of the basal Triassic sediments which

- 4 -

.

 $\times J$

consist of conglomerates, siltstones, sandstones and minor tuff. The basal member is overlain by several hundred feet of dominantly carbonate sediments of the Favret Formation, the Augusta Mountain Formation and the Cone Springs Formation. The uppermost Triassic unit is the detrital sediments of the Osobb Formation.

The Tertiary volcanic rocks in the McCoy area (Fig. 2) range in age from about 36 m.y. to 15 m.y. (McKee and Stewart, 1971). Sedimentary rocks are found at various horizons within the volcanic units. A considerable thickness of sediments overlie the volcanic rocks to the northwest of the McCoy Mine area. West of the McCoy Mine over 2km² of fossil Quaternary travertine is exposed. The travertine lies unconformably upon the eroded Triassic rocks. The travertine dips gently westward and is only slightly dissected.

Tectonically the area has had a long and complex history. The detailed mapping permitted the construction of detailed geologic cross section (Fig. 3). Reasonable approximations of the fault offsets could be made using the displacement of cooling units on Mike Adams geologic map.

Geochemical Studies

The hydrogeochemical analysis of a water sample from the McCoy Mine water well was one of the manifestations which attracted AMAX to the McCoy area. During the exploration drilling in 1980 water was encountered in well 66-8. Table I compares the chemical analyses from McCoy Mine well and exploration well 66-8.

DRILL HOLE MAP

Figure 4. Location map of drill holes used in geochemical study of drill cuttings.

- 9 -

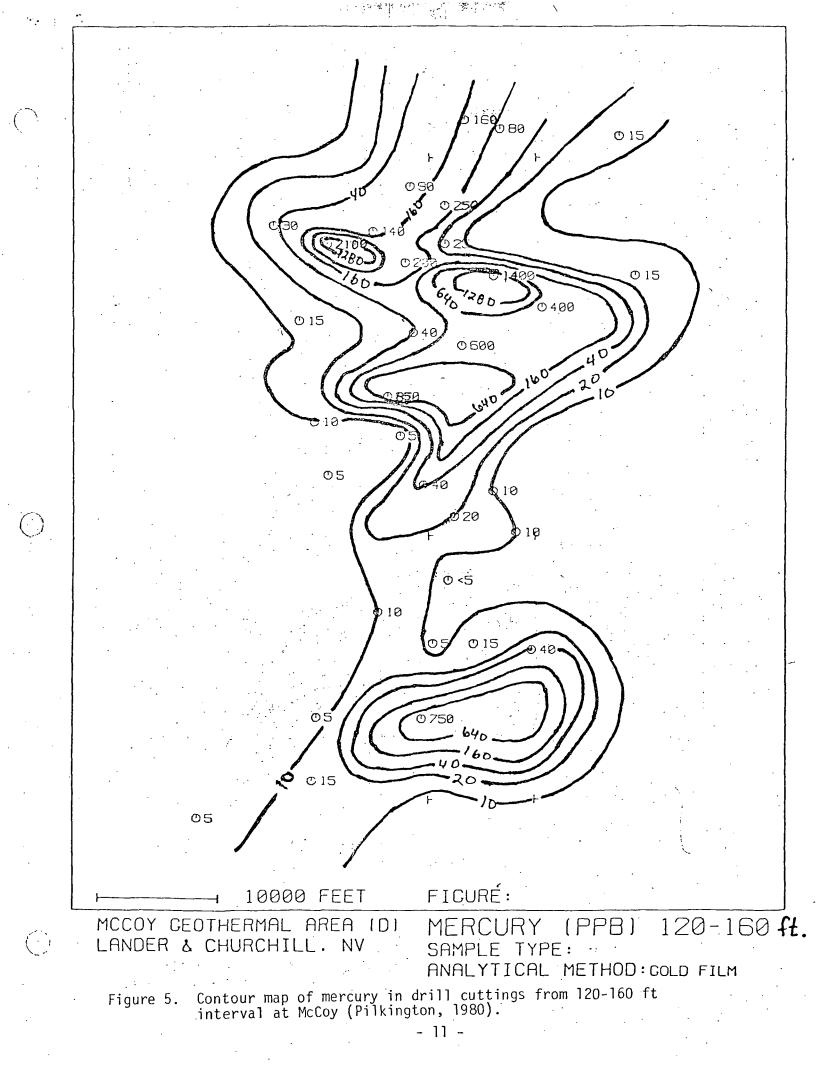

Chemically the waters from Well 66-8 and the McCoy Mine well are sodium bicarbonate waters with projected subsurface temperatures of $98-148^{\circ}$ C based upon the conductive quartz geothermometer and $153^{\circ}-206^{\circ}$ using the N-K-Ca geothermometer.

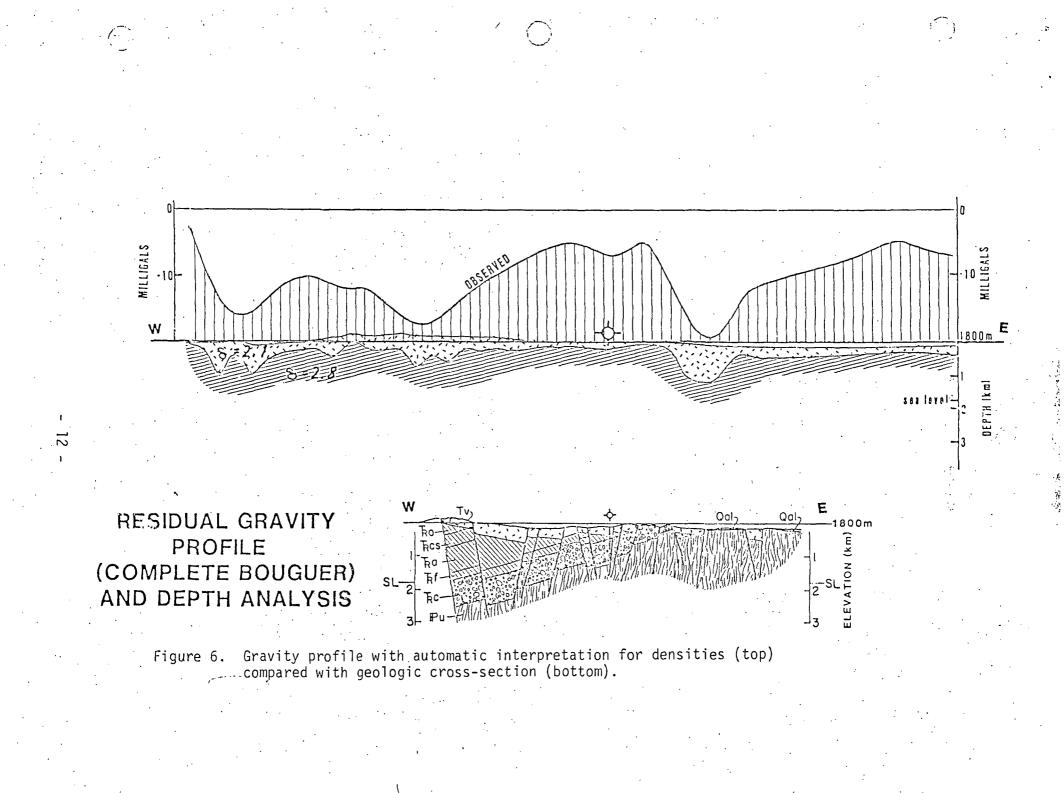

In 1979 Joe Moore of the University of Utah Research Institute proposed to undertake a geochemical study of the drill cuttings from McCoy. AMAX agreed to provide Joe with a split of our samples. UURI prepared composite samples for the intervals of 0-40, 40-80, 80-120 and 120-160 feet for each shallow thermal gradient hole (Figure 4). The geochemical study was done under DOE contract DE-AC 07-80 ID 12079. Multielement geochemical analyses using Inductively Coupled Plasma-Atomic Emission Spectroscopy (Moore 1980) were performed on each composite sample. Preliminary analysis of the data from Joe Moore indicates that Zn, As, Pb, F and Hg show some correlation with the thermal anomaly and also with the known areas of hydrothermal alteration and mineralization. Figure 5 shows the contour map for mercury for the interval 120-160 feet. The contour pattern appears to emphasize certain structural directions and the linear trends become more pronounced with depth (Pilkington, 1980).

Geophysical Studies

A gravity survey of 340 stations was conducted by AMAX and Microgeophysics in 1979 and Fred Berkman has been involved in the analysis of the data. Berkman prepared a residual gravity profile (Complete Bouguer) and depth analysis along an east-west line through well 66-8 (Figure 6) as reported by Lange, 1980. The gravity interpretation (top) is compared with the geologic cross-section by Pilkington (1980) on the bottom part of Figure 6.

- 10 -

A tensor MT survey was run by Terraphysics in February 1980 (Lange, 1980) at the McCoy property (Fig. 7). The location of the lines along which the MT survey was done are shown on Figure 7. The resistivity as deduced by Lange (1980) at a depth of 5 km from the ID inversion of the MT (Te mode) is also shown on Figure 7. The MT section along line C-C' (Figure 8) illustrates the correlation with geology. Lange (1980) believes the MT sees a deep reservoir, (three or more kilometers) along line C-C' which is leaking fluids up the faults bounding the horst block east of well 66-8.

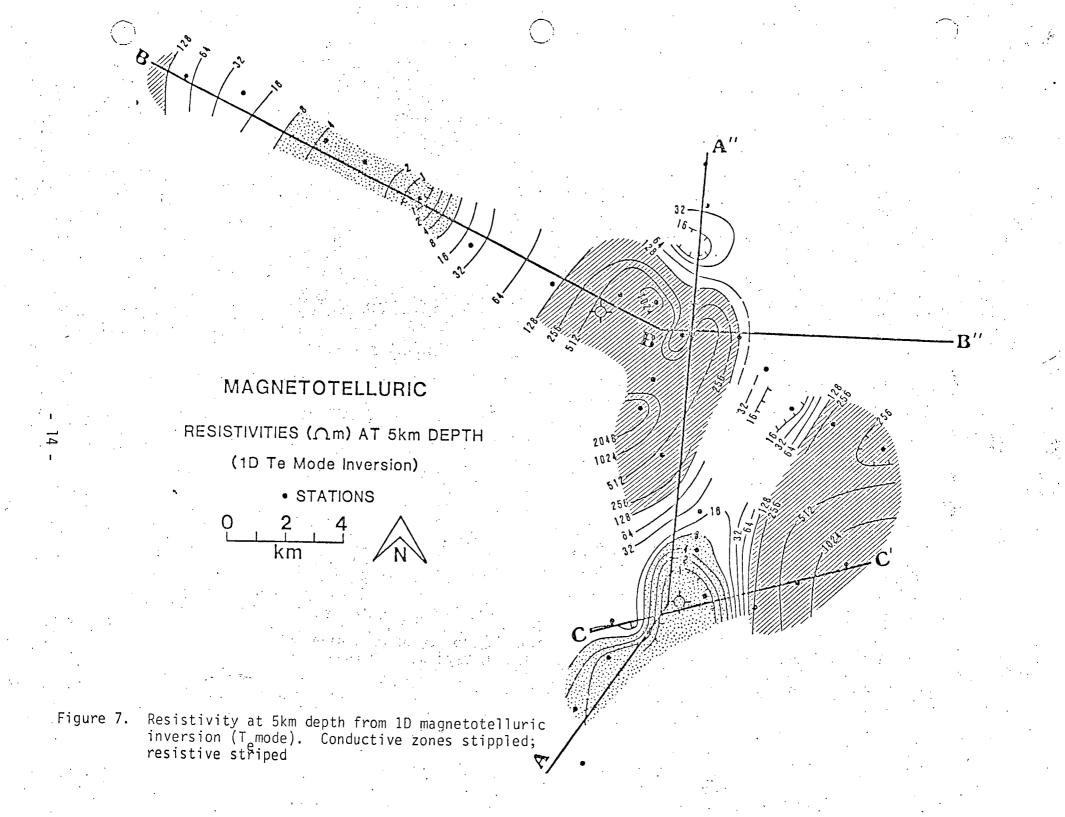

a the second second

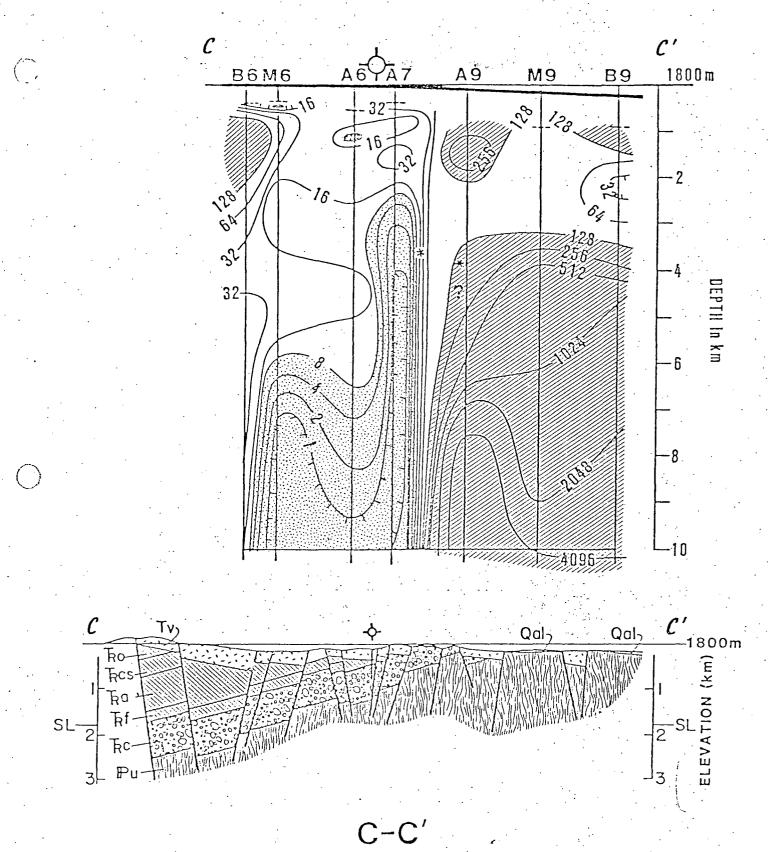

As a part of the Department of Energy's program to stimulate the development of geothermal resources Lawrence Berkley Laboratory (LBL) conducted a survey with the EM-60 frequency domain system over the McCoy prospect (Wilt, M. et al, 1980). The stations for the LBL survey are shown in Figure 9. The survey consisted of 19 frequency-domain electromagnetic soundings from three transmitter loops. A comparison between the EM data from LBL and the AMAX MT data is shown in Figure 10. Wilt et al (1980) conclude that the EM results agree well with the data gathered from well 66-8. A conductor was found at the approximate depths that boiling water was found in the well. The EM does give information on the shallow depths where MT does not give reliable results.

Exploration Drilling

Two intermediate depth exploration wells were completed in 1980. Well 66-8 located in the NWSE Sec. 8 T22N R40E had a TD of 765 meters (2510') and well 14-7 located in the SE NW Sec. 7 T23N R40E had a TD of 613m (2010').

MAGNETOTELLURIC 1-D INVERSION WITH GEOLOGIC PROFILE

Figure 8. MT section (T mode, 1D inversion) along Line C, compared with geologic section - 15 -

()

Both wells were drilled as unit wells for the McCoy Federal Geothermal Unit under a Plan of Operation approved by the U.S. Geological Survey. The generalized drilling plan for the holes was:

1. Move on. Rig up.

2. Drill 17-1/2" hole to +20 ft.

3. Run 20 ft of 13-3/8 conductor pipe, cement.

4. Drill 12-1/4 hole to +505 ft.

5. Run 500 ft of 8-5/8" casing, cement.

6. Install BOP equipment, test.

7. Drill 6-1/4-6-3/4 hole to TD.

8. Run electric logs.

9. Equip hole for flow test if appropriate

10. Equip hole for temperature observation if no suitable production encountered - 3" Black iron pipe installed capped top & bottom filled/water.

Well 66-8 encountered a low temperature geothermal reservoir between 1630 feet and TD. Numerous hot water entries were recorded; with first entry at 1630 feet being the hottest at about 100^oC, or just slightly above boiling for the elevation. The chemistry of the fluids was discussed in the section on geochemical studies. Lost circulation was encountered at several depths below the upper water zone. After completing the well as a thermal observation well it was discovered that drilling mud left in the hole had flowed out into the formation, and the 100^oC water flows into the hole and out one of the lost circulation zones near bottom of hole. Therefore, no valid temperature gradients can be measured. It is proposed to back fill the annulus in 1981 to try and obtain reliable bottom hole temperature data.

- 18 -

Well 14-7 encounterrd lost circulation in the Triassic carbonates at a depth of 409 feet. With considerable difficulty the 8-5/8" casing was set and cemented at a depth of 495 feet. A flow of warm water $\pm 50^{\circ}$ C was encountered just below the casing. Below 800 feet drill blind with no returns to TD. The well was completed as a temperature observation well, but the $\pm 50^{\circ}$ C water at 500 feet is going out into formation somewhere near the bottom of hole so that hole is isothermal below 500 feet.

ABSTRACT

The McCoy geothermal prospect is located at the junction of the Augusta Mountains, Clan Alpine Mountains and the New Pass Range. The prospect was discovered in 1977, and in 1978 was made a part of the Geothermal Reservoir Assessment Case Study Program of the Department of Energy under contract DE-AC 08-79 ET 27010.

Geothermal exploration done during 1981 included additional hydrogeochemical studies and some additional geologic mapping in the southern part of the area. Geophysical work consisted of a dipole-dipole resistivity survey and continued interpretation and analysis of previous data. Exploration drilling included ten shallow thermal gradient holes and two intermediate depth exploration holes. A third hole was started and drilled to a depth of 403 feet and surface casing was run and cemented.

A shallow low-temperature geothermal reservoir was encountered in Permo-Pennsylvanian rocks north of McCoy Mine. The analysis of the exploration continued in an attempt to determine the source area for the thermal fluids.

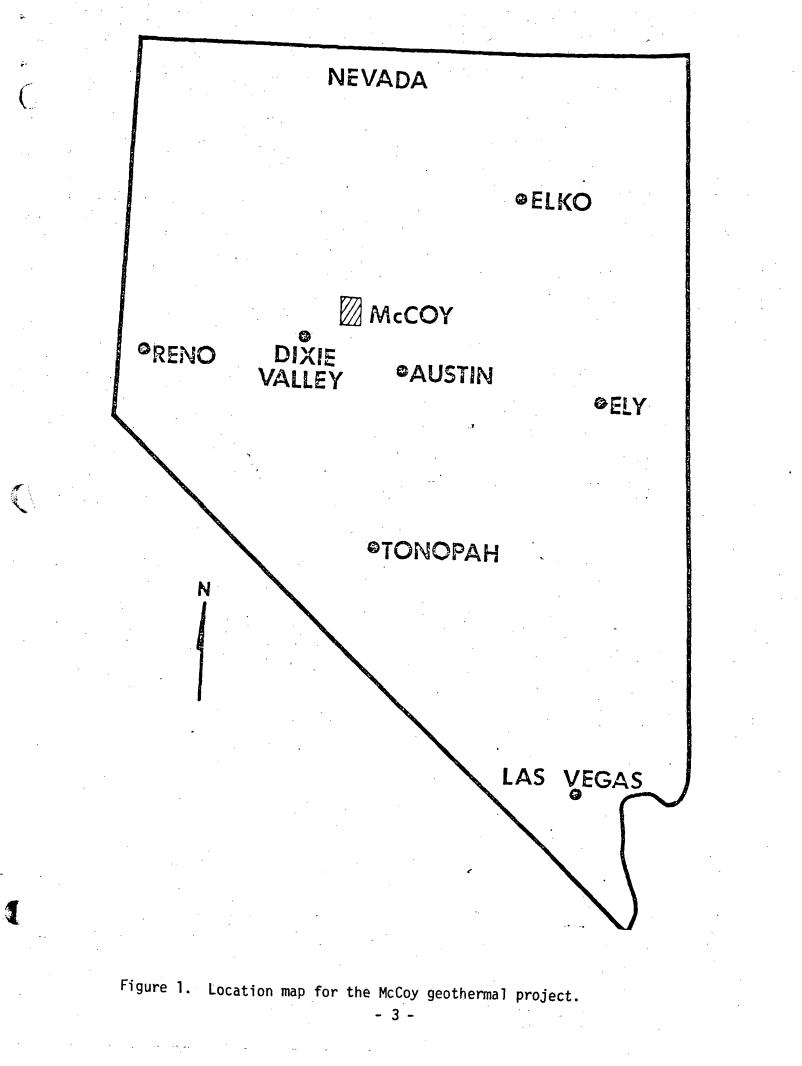

INTRODUCTION

The McCoy geothermal prospect was discovered in 1977 during reconnaissance coverage of Nevada. The prospect was identified by thermal gradient measurements of existing holes and hydrogeochemical analysis of well water from the McCoy Mine water well. The prospect is located approximately 72 kilometers northwest of Austin, Nevada (Figure 1) and can be reached by means of a graded road which leads from U. S. Highway 50.

The McCoy prospect is located at the confluence of the Augusta and Clan Alpine Mountains and the New Pass Range. The prospect straddles the Churchill and Lander County borders.

In 1978 AMAX submitted a proposal in response to the Department of Energy's RFP No. ET-78-R-08-003, Geothermal Reservoir Assessment Case Study, Northern Basin and Range and was awarded a contract providing partial funding for exploration at the property. Detailed results of the work funded through the DOE will be published by the DOE through the University of Utah Research Institute (UURI) under DOE contract DE-AC 08-79 ET 27010.

-2-

EXPLORATION HISTORY

The geothermal exploration partially funded under DOE contract DE ACO8-79 ET 27010 was an integrated approach including geological, geochemical and geophysical studies as well as exploration drilling. For the purpose of this report the exploration will be discussed under exploration methods rather than a chronological description.

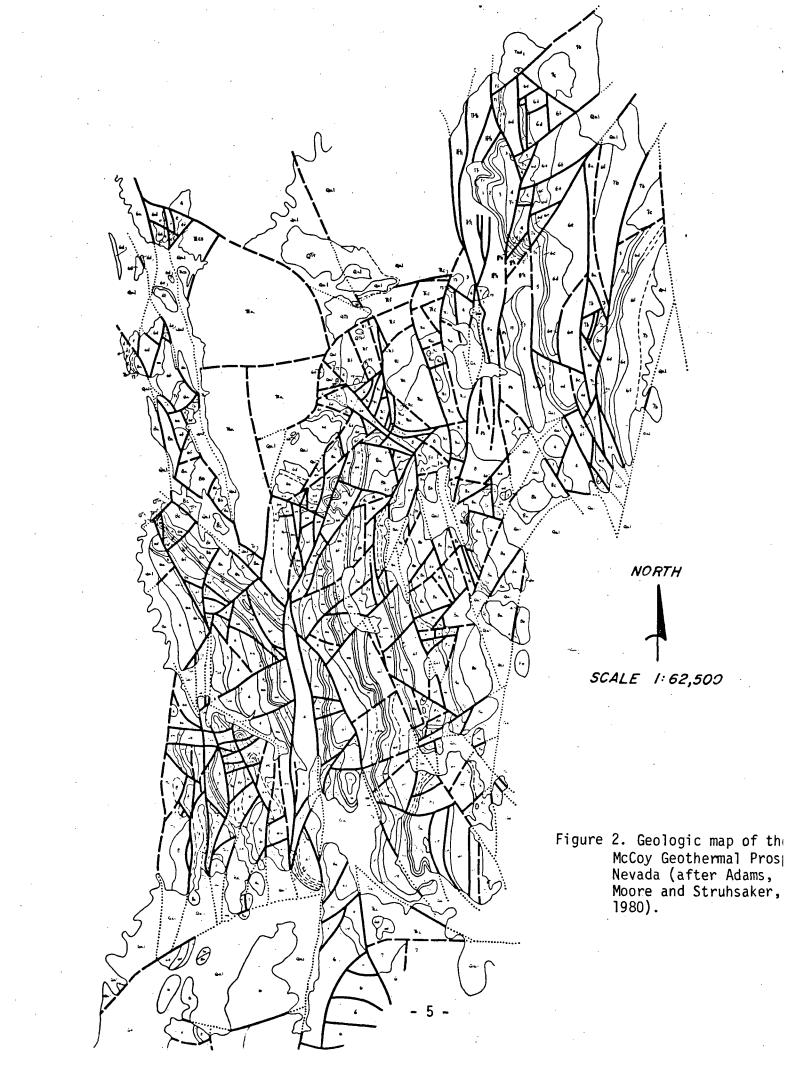

GEOLOGICAL STUDIES

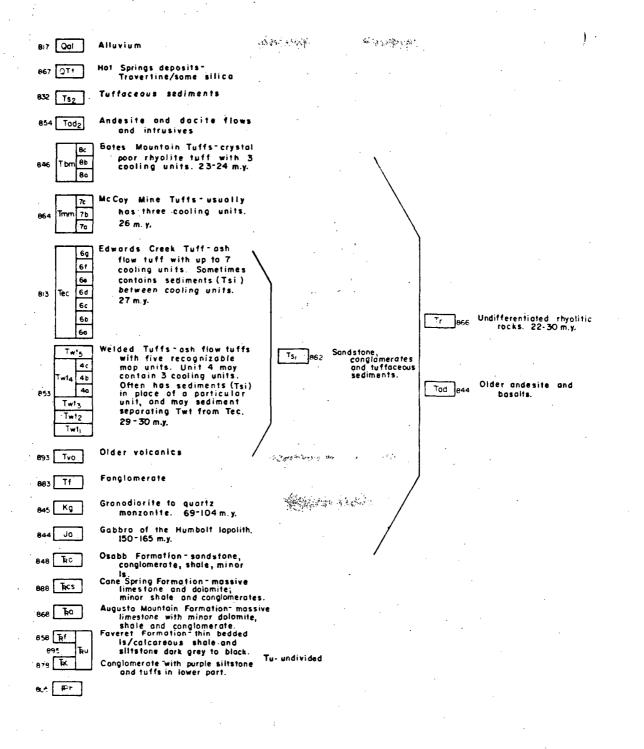

The McCoy geothermal prospect is located at the junction of the Augusta Mountains, the Clan Alpine Mountains and the New Pass range. The area is underlain by Tertiary volcanics and associated sediments, Triassic sediments and Permo-Pennsylvanian eugeosynclinal sediments as shown on the county maps (Stewart, J. H. and McKee, E. H., 1977 and Wilden, R. and Speed, R. L., 1974). The county geologic maps are at a scale of 1:250,000 and, therefore, do not show much detail.

In the late fall of 1979 Joe Moore of the University of Utah Research Institute began a geologic mapping program under DOE contract DEAC 07 - 80 ID 12079. Joe Moore and Eric Struhsacker established the mapping units in the Tertiary volcanics and then Mike Adams of UURI did most of the field mapping in 1980. A detailed geologic map at a scale of 1:24,000 was completed (Fig. 2) in 1980 (Pilkington, 1981). During 1981 the geologic mapping was extended to the south in order to establish a better understanding of the relationship between the Tertiary, Traissic and Permo-Pennsylvanian rocks.

The oldest rocks mapped in the McCoy area are the cherts, volcanics, siltstones, sandstones and minor limestones of the Havallah sequence of Permo-Pennsylvanian age.

-4-

100 miles 110 miles

•

-5-

The rocks were deformed, uplifted and deeply eroded prior to the deposition of the basal Triassic sediments which consist of conglomerates, siltstones, sandstones and minor tuff. The basal member is overlain by several hundred feet of dominantly carbonate sediments of the Favret Formation, the Augusta Mountain Formation and the Cone Springs Formation. The uppermost Triassic unit is the detrital sediments of the Osobb Formation.

The Tertiary volcanic rocks in the McCoy area (Fig. 2) range in age from about 36 m.y. to 15 m.y. (McKee and Stewart, 1971). Sedimentary rocks are found at various horizons within the volcanic units. A considerable thickness of sediments overlie the volcanic rocks to the northwest of the McCoy Mine area. West of the McCoy Mine over 2km² of fossil Quaternary travertine is exposed. The travertine lies unconformably upon the eroded Triassic rocks. The travertine dips gently westward and is only slightly dissected.

Tectonically the area has had a long and complex history. The detailed mapping permitted the construction of detailed geologic cross section (Fig. 3). Reasonable approximations of the fault offsets could be made using the displacement of cooling units on Mike Adams geologic map.

Geochemical Studies

The hydrogeochemical analysis of a water sample from the McCoy Mine water well was one of the manifestations which attracted AMAX to the area. During the exploration drilling in 1980 water was encountered in well 66-8. Table I compares the chemical analyses of the various water samples collected to date.

-13-

Chemically the waters appear to fall into three distinct groups (Fig. 3 and Table II). The majority of non-thermal ground waters are mixed cation-anion waters of low salinity and low SiO_2 content (Type I). The thermal waters in the MCoy areas fall into two groups (Fig. 3 and Table II). The thermal waters from the McCoy Mine area (Type III) are characterized by a higher sodium content (Fig. 3) and a low C1/HCO₃ (Mole) ratio (Table II).

The second groups of thermal waters (Type II) are low to intermediate in sodium content and intermediate to high in potassium content (Fig. 3). Several spring samples fall within the boundary of the Type II waters suggesting a mixing of thermal and meteoric waters. Type II waters tend to have a high $C1/SO_4$ (Mole) ratio (Table II); however, the waters from well 66-8 have $C1/SO_4$ mole ratio values in the same ranges as those from the McCoy Mine area (Table II).

The hydrological regime in the McCoy area appears to be quite complicated. Chemically, two distinct parent fluids are suggested. One parent fluid diluted with meteoric water gives use to Type II waters and the second gives rise to the Type III waters.

Geophysical Studies

A resistivity survey was run by Mining Geophysical Survey, Inc. during the period February 2 to March 3, 1981. Two profiles were run along lines B-B' and C-C' of the MT survey (Pilkington, 1981). The third profile was done along an east-west line to the south (Figure 4).

The low conductivity zone seen spread 2 line C (Fig. 5) may represent the same zone of low conductivity seen in the MT and the EM-60 survey (Pilkington, 1981). The more resistive zones between the center of spread 2 and spread 1 are over the horst block of pre-Tertiary rocks. On line B the near surface resistivity responses are characteristic of inclined blocks of varying resistitivy and probably relate to the block faulting. On line D the area of low resistivity on the west end of the line coincides with an increasing thickness of Tertiary volcanic rocks. The deeper zones of conductive material are probably the same as seen on the MT.

The low resistivity zones may represent conduits for the thermal waters; however, interpretation is complicated by lateral and apparent resistivity effects. Model studies are planned for early 1982.

Exploration Drilling

Two intermediate depth exploration wells were completed in 1981, and a third well was spudded, drilled to 403 feet, cased, and suspended. Well 25-9 located in the NWSW Sec. 9 T22N R40E had a TD of 610 meters (2000') and well 38-9 located in the SESW Sec. 9 T23N R40E had a TD of 620m (2040'). and well 28-18 located in the SWSW Sec. 18 T22NR40E was drilled to 403', cased and suspended.

The exploration wells were drilled as unit wells for the McCoy

-20-

Federal Geothermal Unit under a Plan of Exploration approved by the U.S. Geological Survey. The generalized drilling plan for the holes was:

1. Move on and rig up.

2. Drill 17-1/2" hole to 20 ft.

3. Run 20 ft. surface conductor.

4. Drill 12-1/2" hole to 10% of TD.

5. Run 9 5/8" casing, cement.

6. Install BOP test.

7. Drill 8-5/8" hole to TD.

8. Run electric logs.

9. Run 2 3/8" tubing, fill with water.

10. Cement top 10 feet of annulus.

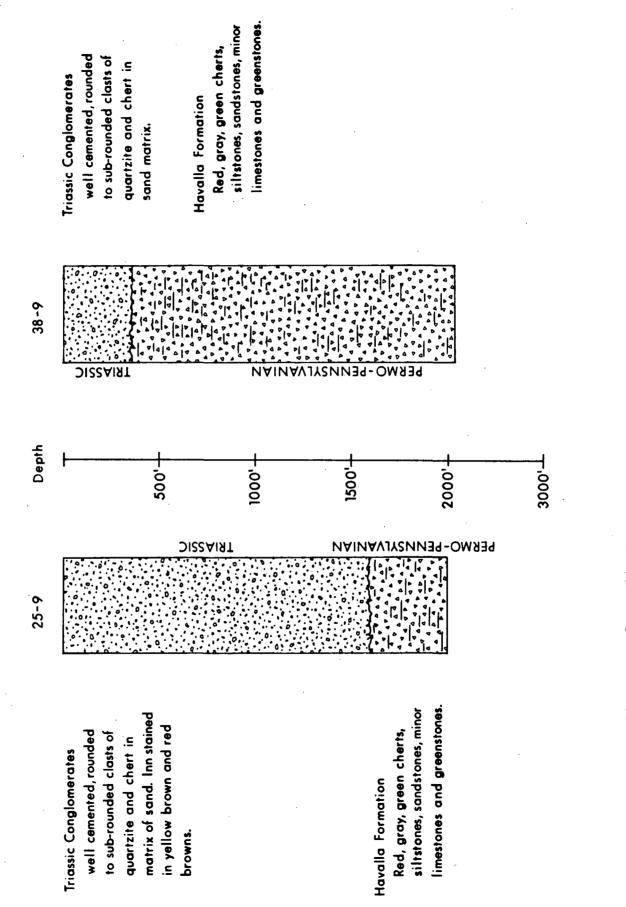

11. Install gate valve on top of tubing.

Generalized stratigraphic sections for wells 25-9 and 38-9 are given in Figure 7. Well 25-9 encountered low temperature geothermal fluids at 1640 feet, 1840 feet and 2000 feet. The maximum temperatuare fluids were at 2000 feet where temperatures are estimated to be 54° C. Chemically the waters are thought to be meteoric waters which circulated to depths sufficient to heat them to the observed temperatures.

Well 38-9 encountered fluids at depths of 550 feet, 1200 feet and 1300 feet. Chemically the geothermal fluids are comparable with those from the McCoy Mine water well.

Well 28-18 will be completed to at least 3000 feet during 1982 in order to effectively test the geophysical anomalies.

ABSTRACT

The McCoy geothermal prospect is located at the junction of the Augusta Mountains, Clan Alpine Mountains and the New Pass Range. The prospect was discovered in 1977, and in 1978 was made a part of the Geothermal Reservoir Assessment Case Study Program of the Department of Energy under contract DE-AC 08-79 ET 27010.

Geothermal exploration done during 1981 included additional hydrogeochemical studies and some additional geologic mapping in the southern part of the area. Geophysical work consisted of a dipole-dipole resistivity survey and continued interpretation and analysis of previous data. Exploration drilling included ten shallow thermal gradient holes and two intermediate depth exploration holes. A third hole was started and drilled to a depth of 403 feet and surface casing was run and cemented.

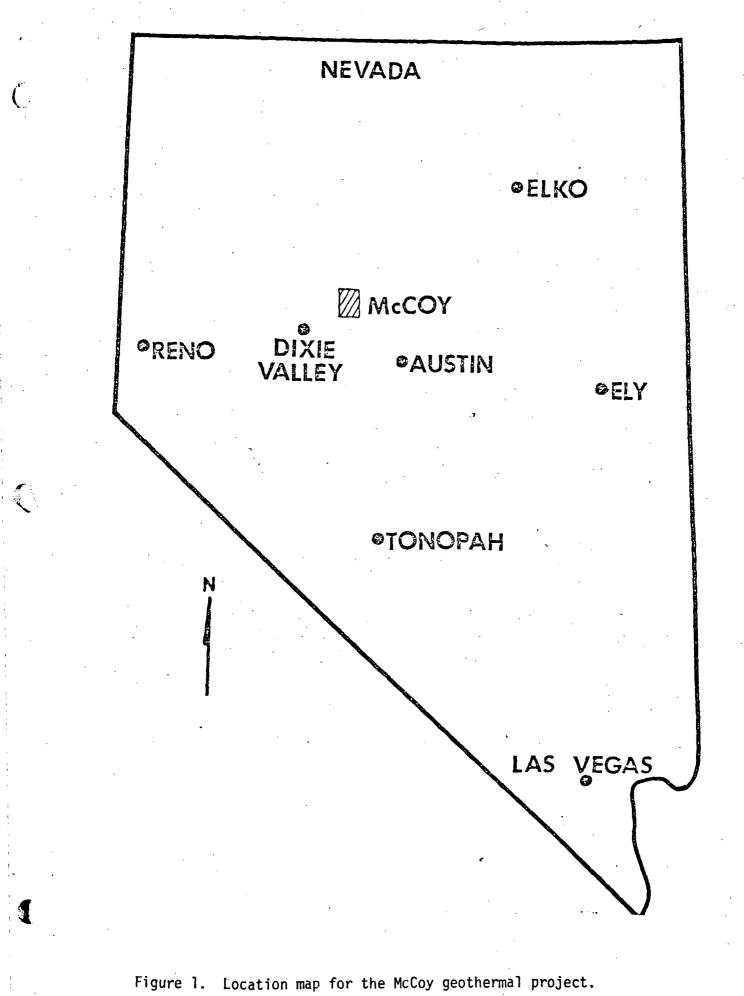

A shallow low-temperature geothermal reservoir was encountered in Permo-Pennsylvanian rocks north of McCoy Mine. The analysis of the exploration continued in an attempt to determine the source area for the thermal fluids.

INTRODUCTION

The McCoy geothermal prospect was discovered in 1977 during reconnaissance coverage of Nevada. The prospect was identified by thermal gradient measurements of existing holes and hydrogeochemical analysis of well water from the McCoy Mine water well. The prospect is located approximately 72 kilometers northwest of Austin, Nevada (Figure 1) and can be reached by means of a graded road which leads from U. S. Highway 50.

The McCoy prospect is located at the confluence of the Augusta and Clan Alpine Mountains and the New Pass Range. The prospect straddles the Churchill and Lander County borders.

In 1978 AMAX submitted a proposal in response to the Department of Energy's RFP No. ET-78-R-08-003, Geothermal Reservoir Assessment Case Study, Northern Basin and Range and was awarded a contract providing partial funding for exploration at the property. Detailed results of the work funded through the DOE will be published by the DOE through the University of Utah Research Institute (UURI) under DOE contract DE-AC 08-79 ET 27010.

- 3 -

EXPLORATION HISTORY

The geothermal exploration partially funded under DOE contract DE ACO8-79 ET 27010 was an integrated approach including geological, geochemical and geophysical studies as well as exploration drilling. For the purpose of this report the exploration will be discussed under exploration methods rather than a chronological description.

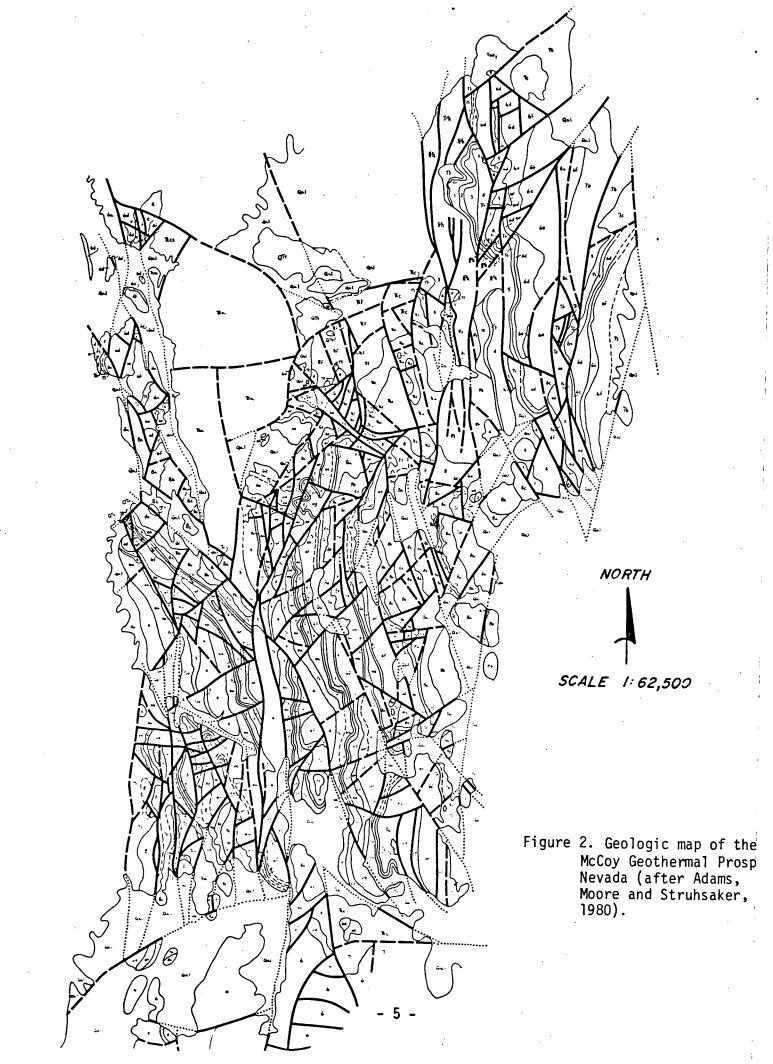

GEOLOGICAL STUDIES

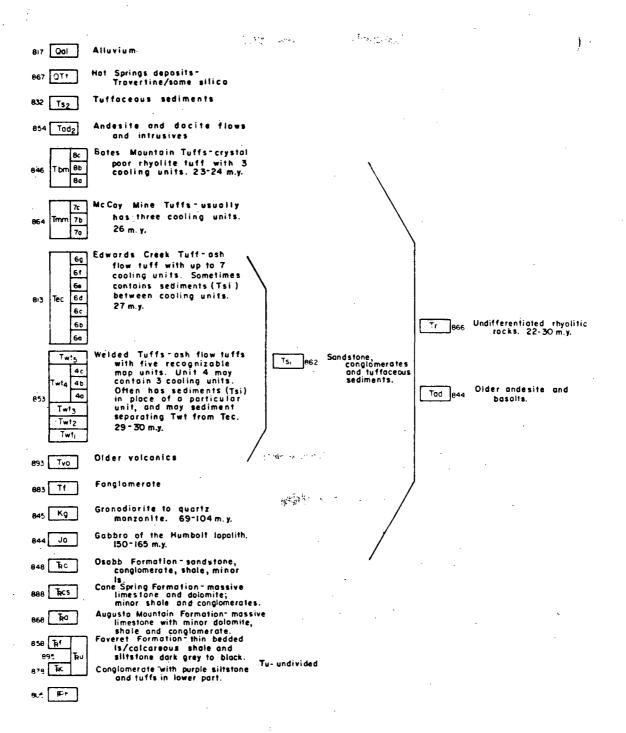

The McCoy geothermal prospect is located at the junction of the Augusta Mountains, the Clan Alpine Mountains and the New Pass range. The area is underlain by Tertiary volcanics and associated sediments, Triassic sediments and Permo-Pennsylvanian eugeosynclinal sediments as shown on the county maps (Stewart, J. H. and McKee, E. H., 1977 and Wilden, R. and Speed, R. L., 1974). The county geologic maps are at a scale of 1:250,000 and, therefore, do not show much detail.

In the late fall of 1979 Joe Moore of the University of Utah Research Institute began a geologic mapping program under DOE contract DEAC 07 - 80 ID 12079. Joe Moore and Eric Struhsacker established the mapping units in the Tertiary volcanics and then Mike Adams of UURI did most of the field mapping in 1980. A detailed geologic map at a scale of 1:24,000 was completed (Fig. 2) in 1980 (Pilkington, 1981). During 1981 the geologic mapping was extended to the south in order to establish a better understanding of the relationship between the Tertiary, Traissic and Permo-Pennsylvanian rocks.

The oldest rocks mapped in the McCoy area are the cherts, volcanics, siltstones, sandstones and minor limestones of the Havallah sequence of Permo-Pennsylvanian age.

-4-

1.41

-5-

·

The rocks were deformed, uplifted and deeply eroded prior to the deposition of the basal Triassic sediments which consist of conglomerates, siltstones, sandstones and minor tuff. The basal member is overlain by several hundred feet of dominantly carbonate sediments of the Favret Formation, the Augusta Mountain Formation and the Cone Springs Formation. The uppermost Triassic unit is the detrital sediments of the Osobb Formation.

The Tertiary volcanic rocks in the McCoy area (Fig. 2) range in age from about 36 m.y. to 15 m.y. (McKee and Stewart, 1971). Sedimentary rocks are found at various horizons within the volcanic units. A considerable thickness of sediments overlie the volcanic rocks to the northwest of the McCoy Mine area. West of the McCoy Mine over 2km² of fossil Quaternary travertine is exposed. The travertine lies unconformably upon the eroded Triassic rocks. The travertine dips gently westward and is only slightly dissected.

Tectonically the area has had a long and complex history. The detailed mapping permitted the construction of detailed geologic cross section (Fig. 3). Reasonable approximations of the fault offsets could be made using the displacement of cooling units on Mike Adams geologic map.

Geochemical Studies

The hydrogeochemical analysis of a water sample from the McCoy Mine water well was one of the manifestations which attracted AMAX to the area. During the exploration drilling in 1980 water was encountered in well 66-8. Table I compares the chemical analyses of the various water samples collected to date.

Chemically the waters appear to fall into three distinct groups (Fig. 3 and Table II). The majority of non-thermal ground waters are mixed cation-anion waters of low salinity and low SiO_2 content (Type I). The thermal waters in the MCoy areas fall into two groups (Fig. 3 and Table II). The thermal waters from the McCoy Mine area (Type III) are characterized by a higher sodium content (Fig. 3) and a low Cl/HCO₃ (Mole) ratio (Table II).

The second groups of thermal waters (Type II) are low to intermediate in sodium content and intermediate to high in potassium content (Fig. 3). Several spring samples fall within the boundary of the Type II waters suggesting a mixing of thermal and meteoric waters. Type II waters tend to have a high $C1/SO_4$ (Mole) ratio (Table II); however, the waters from well 66-8 have $C1/SO_4$ mole ratio values in the same ranges as those from the McCoy Mine area (Table II).

The hydrological regime in the McCoy area appears to be quite complicated. Chemically, two distinct parent fluids are suggested. One parent fluid diluted with meteoric water gives use to Type II waters and the second gives rise to the Type III waters.

Geophysical Studies

A resistivity survey was run by Mining Geophysical Survey, Inc. during the period February 2 to March 3, 1981. Two profiles were run along lines B-B' and C-C' of the MT survey (Pilkington, 1981). The third profile was done along an east-west line to the south (Figure 4).

The low conductivity zone seen spread 2 line C (Fig. 5) may represent the same zone of low conductivity seen in the MT and the EM-60 survey (Pilkington, 1981). The more resistive zones between the center of spread 2 and spread 1 are over the horst block of pre-Tertiary rocks. On line B the near surface resistivity responses are characteristic of inclined blocks of varying resistitivy and probably relate to the block faulting. On line D the area of low resistivity on the west end of the line coincides with an increasing thickness of Tertiary volcanic rocks. The deeper zones of conductive material are probably the same as seen on the MT.

The low resistivity zones may represent conduits for the thermal waters; however, interpretation is complicated by lateral and apparent resistivity effects. Model studies are planned for early 1982.

Exploration Drilling

Two intermediate depth exploration wells were completed in 1981, and a third well was spudded, drilled to 403 feet, cased, and suspended. Well 25-9 located in the NWSW Sec. 9 T22N R40E had a TD of 610 meters (2000') and well 38-9 located in the SESW Sec. 9 T23N R40E had a TD of 620m (2040'). and well 28-18 located in the SWSW Sec. 18 T22NR40E was drilled to 403', cased and suspended.

The exploration wells were drilled as unit wells for the McCoy

-17-

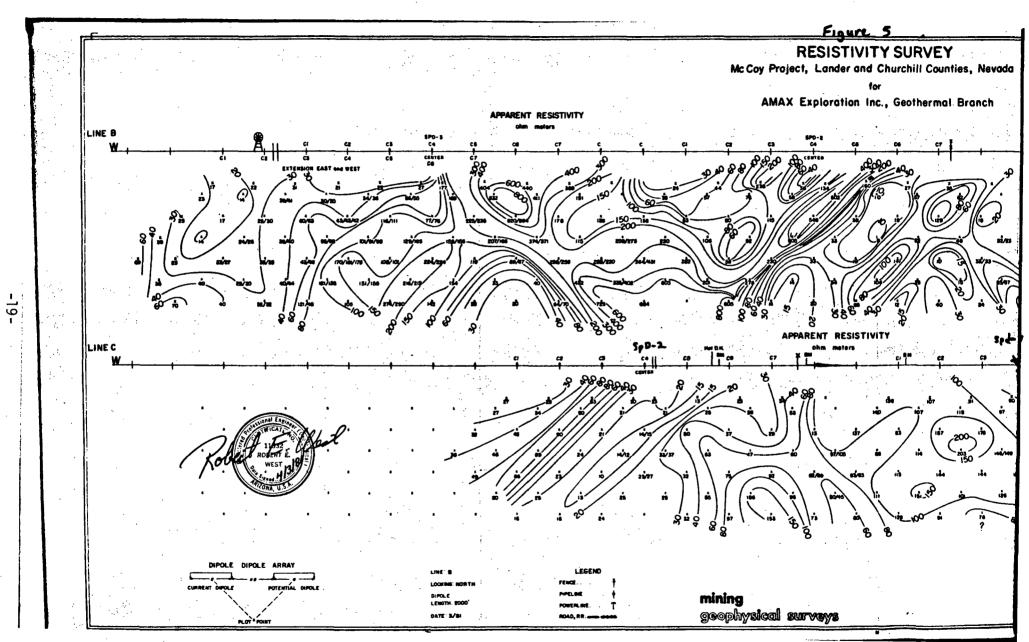

Figure 5. Resistivity survey McCoy Project, Nevada Line B and C

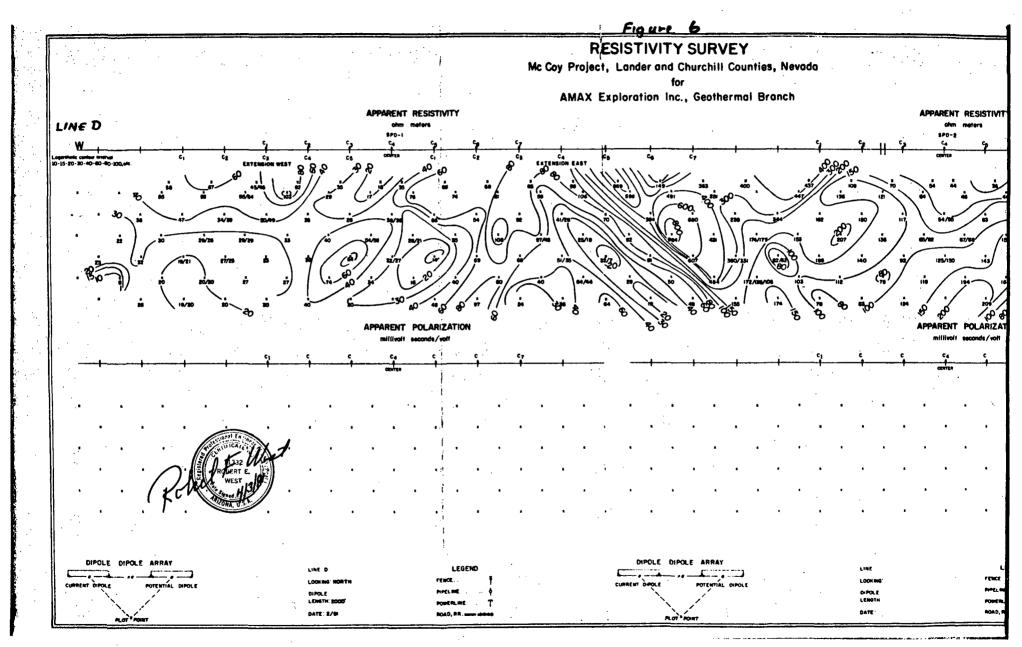

Figure 6. Resistivity survey McCoy Project, Nevada Line D

-20-

Federal Geothermal Unit under a Plan of Exploration approved by the U.S. Geological Survey. The generalized drilling plan for the holes was:

1. Move on and rig up.

2. Drill 17-1/2" hole to 20 ft.

3. Run 20 ft. surface conductor.

4. Drill 12-1/2" hole to 10% of TD.

5. Run 9 5/8" casing, cement.

6. Install BOP test.

7. Drill 8-5/8" hole to TD.

8. Run electric logs.

9. Run 2 3/8" tubing, fill with water.

10. Cement top 10 feet of annulus.

11. Install gate valve on top of tubing.

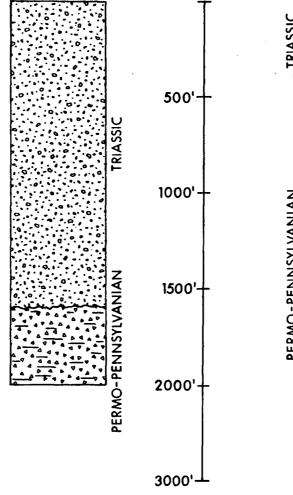

Generalized stratigraphic sections for wells 25-9 and 38-9 are given in Figure 7. Well 25-9 encountered low temperature geothermal fluids at 1640 feet, 1840 feet and 2000 feet. The maximum temperatuare fluids were at 2000 feet where temperatures are estimated to be 54° C. Chemically the waters are thought to be meteoric waters which circulated to depths sufficient to heat them to the observed temperatures.

Well 38-9 encountered fluids at depths of 550 feet, 1200 feet and 1300 feet. Chemically the geothermal fluids are comparable with those from the McCoy Mine water well.

Well 28-18 will be completed to at least 3000 feet during 1982 in order to effectively test the geophysical anomalies.

ABSTRACT

The McCoy geothermal prospect is located at the junction of the Augusta Mountains, Clan Alpine Mountains and the New Pass Range. The prospect was discovered in 1977, and in 1978 was made a part of the Geothermal Reservoir Assessment Case Study Program of the Department of Energy under contract DE-AC 08-79 ET 27010.

Geothermal exploration done during 1981 included additional hydrogeochemical studies and some additional geologic mapping in the southern part of the area. Geophysical work consisted of a dipole-dipole resistivity survey and continued interpretation and analysis of previous data. Exploration drilling included ten shallow thermal gradient holes and two intermediate depth exploration holes. A third hole was started and drilled to a depth of 403 feet and surface casing was run and cemented.

A shallow low-temperature geothermal reservoir was encountered in Permo-Pennsylvanian rocks north of McCoy Mine. The analysis of the exploration continued in an attempt to determine the source area for the thermal fluids.

INTRODUCTION

The McCoy geothermal prospect was discovered in 1977 during reconnaissance coverage of Nevada. The prospect was identified by thermal gradient measurements of existing holes and hydrogeochemical analysis of well water from the McCoy Mine water well. The prospect is located approximately 72 kilometers northwest of Austin, Nevada (Figure 1) and can be reached by means of a graded road which leads from U. S. Highway 50.

The McCoy prospect is located at the confluence of the Augusta and Clan Alpine Mountains and the New Pass Range. The prospect straddles the Churchill and Lander County borders.

In 1978 AMAX submitted a proposal in response to the Department of Energy's RFP No. ET-78-R-08-003, Geothermal Reservoir Assessment Case Study, Northern Basin and Range and was awarded a contract providing partial funding for exploration at the property. Detailed results of the work funded through the DOE will be published by the DOE through the University of Utah Research Institute (UURI) under DOE contract DE-AC 08-79 ET 27010.

EXPLORATION HISTORY

The geothermal exploration partially funded under DOE contract DE ACO8-79 ET 27010 was an integrated approach including geological, geochemical and geophysical studies as well as exploration drilling. For the purpose of this report the exploration will be discussed under exploration methods rather than a chronological description.

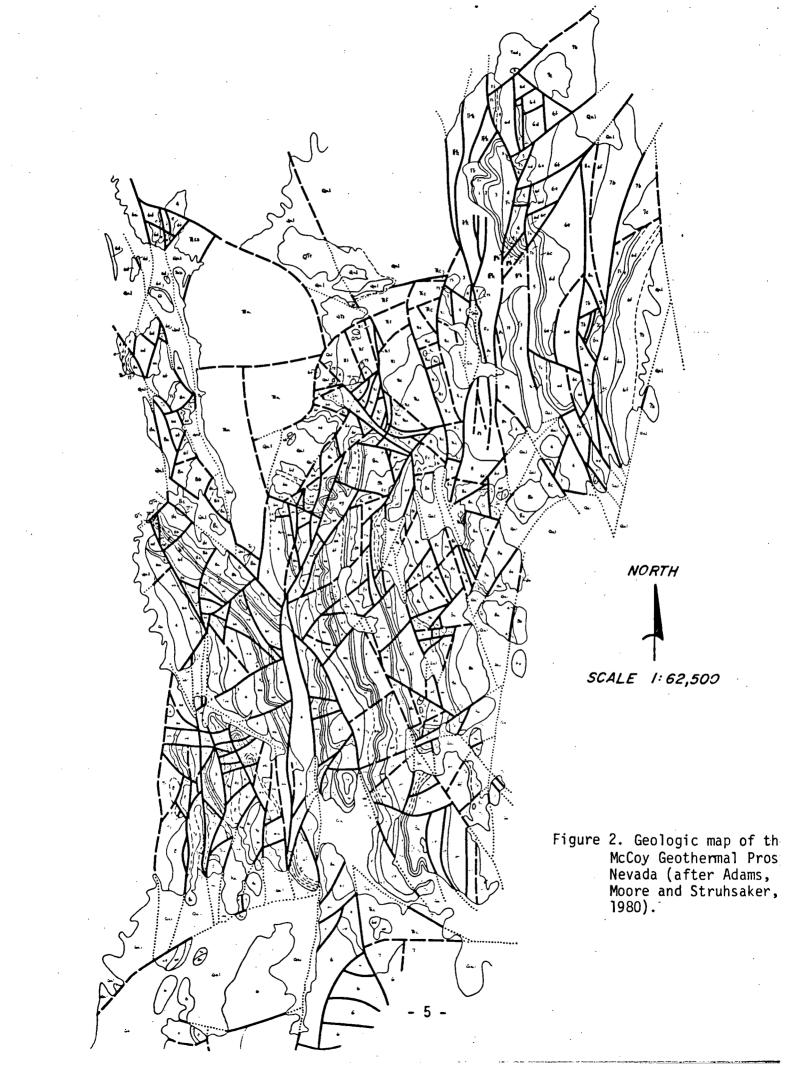

GEOLOGICAL STUDIES

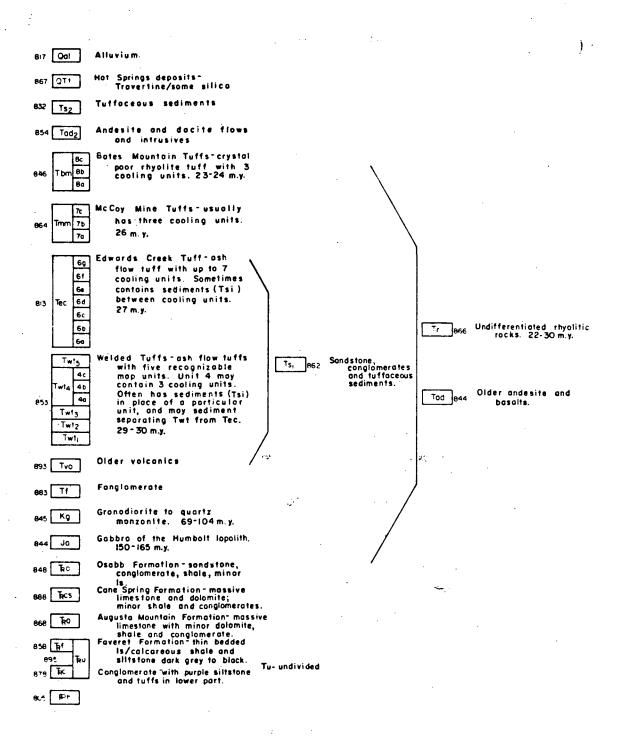

The McCoy geothermal prospect is located at the junction of the Augusta Mountains, the Clan Alpine Mountains and the New Pass range. The area is underlain by Tertiary volcanics and associated sediments, Triassic sediments and Permo-Pennsylvanian eugeosynclinal sediments as shown on the county maps (Stewart, J. H. and McKee, E. H., 1977 and Wilden, R. and Speed, R. L., 1974). The county geologic maps are at a scale of 1:250,000 and, therefore, do not show much detail.

In the late fall of 1979 Joe Moore of the University of Utah Research Institute began a geologic mapping program under DOE contract DEAC 07 - 80 ID 12079. Joe Moore and Eric Struhsacker established the mapping units in the Tertiary volcanics and then Mike Adams of UURI did most of the field mapping in 1980. A detailed geologic map at a scale of 1:24,000 was completed (Fig. 2) in 1980 (Pilkington, 1981). During 1981 the geologic mapping was extended to the south in order to establish a better understanding of the relationship between the Tertiary, Traissic and Permo-Pennsylvanian rocks.

The oldest rocks mapped in the McCoy area are the cherts, volcanics, siltstones, sandstones and minor limestones of the Havallah sequence of Permo-Pennsylvanian age.

www.ure.e

-5-

The rocks were deformed, uplifted and deeply eroded prior to the deposition of the basal Triassic sediments which consist of conglomerates, siltstones, sandstones and minor tuff. The basal member is overlain by several hundred feet of dominantly carbonate sediments of the Favret Formation, the Augusta Mountain Formation and the Cone Springs Formation. The uppermost Triassic unit is the detrital sediments of the Osobb Formation.

The Tertiary volcanic rocks in the McCoy area (Fig. 2) range in age from about 36 m.y. to 15 m.y. (McKee and Stewart, 1971). Sedimentary rocks are found at various horizons within the volcanic units. A considerable thickness of sediments overlie the volcanic rocks to the northwest of the McCoy Mine area. West of the McCoy Mine over 2km^2 of fossil Quaternary travertine is exposed. The travertine lies unconformably upon the eroded Triassic rocks. The travertine dips gently westward and is only slightly dissected.

Tectonically the area has had a long and complex history. The detailed mapping permitted the construction of detailed geologic cross section (Fig. 3). Reasonable approximations of the fault offsets could be made using the displacement of cooling units on Mike Adams geologic map.

Geochemical Studies

The hydrogeochemical analysis of a water sample from the McCoy Mine water well was one of the manifestations which attracted AMAX to the area. During the exploration drilling in 1980 water was encountered in well 66-8. Table I compares the chemical analyses of the various water samples collected to date.

Chemically the waters appear to fall into three distinct groups (Fig. 3 and Table II). The majority of non-thermal ground waters are mixed cation-anion waters of low salinity and low SiO_2 content (Type I). The thermal waters in the MCoy areas fall into two groups (Fig. 3 and Table II). The thermal waters from the McCoy Mine area (Type III) are characterized by a higher sodium content (Fig. 3) and a low Cl/HCO₃ (Mole) ratio (Table II).

The second groups of thermal waters (Type II) are low to intermediate in sodium content and intermediate to high in potassium content (Fig. 3). Several spring samples fall within the boundary of the Type II waters suggesting a mixing of thermal and meteoric waters. Type II waters tend to have a high $C1/SO_4$ (Mole) ratio (Table II); however, the waters from well 66-8 have $C1/SO_4$ mole ratio values in the same ranges as those from the McCoy Mine area (Table II).

The hydrological regime in the McCoy area appears to be quite complicated. Chemically, two distinct parent fluids are suggested. One parent fluid diluted with meteoric water gives use to Type II waters and the second gives rise to the Type III waters.

Geophysical Studies

A resistivity survey was run by Mining Geophysical Survey, Inc. during the period February 2 to March 3, 1981. Two profiles were run along lines B-B' and C-C' of the MT survey (Pilkington, 1981). The third profile was done along an east-west line to the south (Figure 4).

The low conductivity zone seen spread 2 line C (Fig. 5) may represent the same zone of low conductivity seen in the MT and the EM-60 survey (Pilkington, 1981). The more resistive zones between the center of spread 2 and spread 1 are over the horst block of pre-Tertiary rocks. On line B the near surface resistivity responses are characteristic of inclined blocks of varying resistitivy and probably relate to the block faulting. On line D the area of low resistivity on the west end of the line coincides with an increasing thickness of Tertiary volcanic rocks. The deeper zones of conductive material are probably the same as seen on the MT.

The low resistivity zones may represent conduits for the thermal waters; however, interpretation is complicated by lateral and apparent resistivity effects. Model studies are planned for early 1982.

Exploration Drilling

Two intermediate depth exploration wells were completed in 1981, and a third well was spudded, drilled to 403 feet, cased, and suspended. Well 25-9 located in the NWSW Sec. 9 T22N R40E had a TD of 610 meters (2000') and well 38-9 located in the SESW Sec. 9 T23N R40E had a TD of 620m (2040'). and well 28-18 located in the SWSW Sec. 18 T22NR40E was drilled to 403', cased and suspended.

The exploration wells were drilled as unit wells for the McCoy

Federal Geothermal Unit under a Plan of Exploration approved by the U.S. Geological Survey. The generalized drilling plan for the holes was:

1. Move on and rig up.

2. Drill 17-1/2" hole to 20 ft.

3. Run 20 ft. surface conductor.

4. Drill 12-1/2" hole to 10% of TD.

5. Run 9 5/8" casing, cement.

6. Install BOP test.

7. Drill 8-5/8" hole to TD.

8. Run electric logs.

9. Run 2 3/8" tubing, fill with water.

10. Cement top 10 feet of annulus.

11. Install gate valve on top of tubing.

Generalized stratigraphic sections for wells 25-9 and 38-9 are given in Figure 7. Well 25-9 encountered low temperature geothermal fluids at 1640 feet, 1840 feet and 2000 feet. The maximum temperatuare fluids were at 2000 feet where temperatures are estimated to be 54° C. Chemically the waters are thought to be meteoric waters which circulated to depths sufficient to heat them to the observed temperatures.

Well 38-9 encountered fluids at depths of 550 feet, 1200 feet and 1300 feet. Chemically the geothermal fluids are comparable with those from the McCoy Mine water well.

Well 28-18 will be completed to at least 3000 feet during 1982 in order to effectively test the geophysical anomalies.
