SEISMIC DATA EVALUATION OF GEOTHERMAL POTENTIAL ON SODA LAKE

David Worthen

SOURCES

A compilation of sources to date indicates that there are:

1. Geological descriptions and maps of the area performed for the USGS (1964).
2. A migrated contour map of a near surface phantom horizon taken from a shallow reflection seismic survey. This survey used a weight dropping technique for the source, and a single channel field summer for the receiver. It covered approximately a 15 square mile area with a rectangular grid of 7 lines (1975).
3. Four wells with logs and a geological evaluation of core samples (1975). Carson sink #1, 1-29, 44-5, and 36-78.
4. A grid of 3, 12-fold lines using dynamite at a hole depth of 150' (1978).

EVALUATION

An evaluation of three 12-fold lines confirms the existence of the angular unconformity postulated on the earlier seismic work, and better defines the faulting pattern above the angular unconformity.

However, the essential results which indicates the best surface position for drilling is a deep (4000') band of energy below which there appears to be no reflections. This band of energy indicates the possibility of a basement to the sedimentary section which the core samples from the wells seem to confirm.

This basement appears at one time to have been a dome or ridge which was faulted with some 2000' throw, followed by a period of deposition. A major event followed by deposition created the unconformity. The scenario then indicates a period of deposition terminating with pressures near the apex of the anticline which produced a distinctive faulting pattern near the surface (Line 3). This is clearly indicated by a contour map of the unconformity.

To clarify the prime result, a phantom horizon of the basement band was mapped and contoured along with a map and contour of a phantom of a near surface band. This map can perhaps be used with the aid of areal photos to verify or substantiate the strikes of the near surface faults.

Processing and Quality of Seismic Data

The recent seismic data was recorded with an 18 CPS low cut filter and a 124 CPS high cut. If one uses the maximum resolution criterion of 1/3 of a wavelength, then the smallest fault resolution possible would be 16' or approximately 5 mils on the shallow section.

$$v = f\lambda \quad \lambda = 50'$$

$$6000 = 125\lambda \quad 1/3\lambda = 16'$$

The fault displacements on line three appear to be:

SHOT POINT	APPROXIMATE 2 WAY RECORD TIME	ONE WAY RECORD TIME	RECORD TIME CORRECTED TO SURFACE	DISPLACEMENT TIME		DISPLACEMENT

A note about the processing sequence which has relevance to the detection of faults and position of their boundaries indicates that:

1. There appears to have been no band limited filter applied after deconvolution (Deconvolution can add spurious high frequencies to the data).
2. Automatic statics appeared to have been applied. The band of high quality data over which a correlation gate could have been placed seems limited and perhaps some small faults could have been smoothed over depending upon the intricacies of the automatic static program.
3. No diffraction-summation migration program was run on the data which may be critical to the exact location of faulting interfaces.

GENERAL COMMENTS

The 12 fold deconvolved seismic data is superior to the other sources in the detection and location of faults near the surface. But because of velocity errors or statics problems, only one horizon is mappable.

The only available velocity information to convert time to depth is an instantaneous velocity function computed from the sonic log on the Chevron Phillips Soda Lake No. 1-29 well. ($V_i = 5000 + 4.16Z$ for $Z < 1200$; $V_i = 10,000$ for > 1200 ft.)

This function was used to generate a table of one-way time versus depth in feet for depth conversion. The two way times for the horizon to be mapped were picked from the seismic sections and listed for variously spaced (Tables 1, 2, 6, 7, 8) shot-points. The times were halved and looked up in the computer printout for a corresponding depth.

The depths below 3800 ft (reference plane) and above 2600 ft obey the relationship.

$$V_i = 5000 + 4.16Z$$

$$\frac{dZ}{dt} = 5000 + 4.16Z$$

$$\frac{dZ}{5000 + 4.16Z} = dt$$

$$\int \frac{dZ}{5000 + 4.16Z} = t + C$$

$$\frac{1}{4.16} \ln(5000 + 4.16Z) = t + C$$

$$\ln(5000 + 4.16Z) = 4.16(t + C)$$

$$e^{4.16(t + C)} = 5000 + 4.16Z$$

$$t=0 \quad Z=0$$

$$e^{4.16C} = 5000$$

$$C = 2.0474$$

$$\frac{(e^{4.16(t + C)} - 5000)}{4.16} = Z$$

One way time, depth below 3800 ft; depth below the surface (4000 ft); and the actual elevation of the horizon are listed on table 3, 4, and 5. The elevations were posted on a map and faults from regions where there is no current data were transferred from the shallows seismic survey data. A similar procedure was followed for phantoms constructed on a shallow event and a band of deep energy. (Tables 9, 10, 11, 12, 13, 14)
