## CHAPTER IX

### GENERAL DESCRIPTIONS OF THE MINERAL SPRINGS

BY  
R. D. GEORGE

#### ARVADA, JEFFERSON COUNTY

1. Macalso Sulphate Water, also called Golden Lithia Water, Kearney Ranch, 4 miles northwest of Arvada.

There was formerly a spring, but the digging of a well 65 feet deep diverted the water, and it is now taken from the well. Plans have been made for bottling and shipping the waters and for erecting the necessary buildings for a resort. The surface formation is the Arapahoe of Tertiary Age.

#### CONUNDRUM SPRINGS NEAR ASPEN, PITKIN COUNTY

2. The springs are in an area of Carboniferous rocks at timber line, near the head of Conundrum Creek, in the Sopris National Forest. They are about 14 miles south of Aspen, the most convenient railway point. There are two groups of springs issuing from the same limestone ledge, but only the southern group is important. This consists of two fairly large springs and several small ones. The largest spring has a flow estimated at 25 gallons per minute. The temperature of the water is 100° F.

#### AUSTIN AND VICINITY, DELTA COUNTY

3. *Cold Sulphur Spring* is near the entrance to the Black Canyon, about 450 yards up the river from the State Bridge. The waters issue from a Cretaceous sandstone (probably Dakota), in an area of rounded shale hills. The flow is about 15 gallons per minute. The water is rather strongly mineralized and is accompanied by much carbon dioxide, and some hydrogen sulphide.

4. *Alkali Spring*. This is really a group of small springs between the Sulphur Spring and the State Bridge. The water issues from a sandstone (probably Dakota), at a point about 40 or 50 feet above the Sulphur Spring. The total flow is small, but proper excavation would probably increase it.

4a. *Black Canyon Well*. The well was drilled by the Black Canyon Oil Company on an anticline a short distance up the river from the State Bridge, near Austin. At a depth of 225 feet it developed a strong artesian flow of highly saline water accompanied by much carbon dioxide. The analysis of the brine was made by Von Schulz and Low.

This is the most highly mineralized water analyzed for this report. It is also prominent in the matter of its lithium content.

#### AVALANCHE AND VICINITY, PITKIN COUNTY

The springs are along the Crystal River in the vicinity of Avalanche, a station on the Crystal River Railway in Pitkin County. The springs are in an area of Carboniferous and Permian sedimentary rocks cut by a diorite intrusion.

The flow of several of the springs is large, and that of the others could be considerably increased by proper excavation.

5. *The Bath House Spring* issues from the diorite on the very bank of the river at Avalanche Station, and is developed by a log bath house and a pool.

6. *The Cold Iron Spring* is located in a swampy area on the east bank of the river,  $\frac{1}{2}$  to  $\frac{3}{4}$  of a mile below the station. It has formed a large deposit, but now issues at a point nearer the river.

7. *The Hot Iron Spring* is in a meadow about  $\frac{1}{4}$  mile up the river on the east bank. Gas accompanies the water. Much salt is deposited in the marshy area about the spring. The content of ferrous bicarbonate is quite large.

8. This spring is about 100 yards above the last, but the notable differences in the basic elements make it clear that they draw their waters from different sources. The iron bicarbonate content is like that of the preceding spring.

9. *River Spring* is on the very brink of the river at Avalanche, and is covered by the river at high water. The flow is small, but could be increased.

10. *Hot Sulphur Spring* is about 50 yards below the Bath House Spring but on the opposite side of the river. The opening has been covered by slide rock from the diorite and the water flows through the base of the talus.

#### BARR AND VICINITY, ADAMS COUNTY

11. *Colorado Carlsbad Water*. The water comes from a well 90 feet deep, located 6 miles east of Barr. The place was once

203. *The Mound Spring* is about 50 yards up the hill from the Iron Spring. A mound of spring-deposited material 100 feet wide and 10 to 12 feet high represents the work of springs now reduced to mere seepages. There are several openings in the mound and from these water seeps and gas bubbles. The waters of these springs were believed to contain arsenic, but the analysis did not show its presence.

Waters of the Bubbling Spring, the spring across the gulch and the Mound Spring are very similar in composition, and probably have a common origin. The water of Clear Spring is quite similar to these, but much less strongly mineralized. That of the Iron Spring belongs to the same general class, but is comparatively weakly mineralized. It differs in details from all the others.

204. *The Watson Artesian Well* is located 1 mile south and  $\frac{1}{2}$  mile east of Siloam post office. The water flows from a 10-inch pipe which stands about 2 feet out of the ground. The yield is very large and the water is used for irrigation. Gas is abundant.

#### SILVERTON, SAN JUAN COUNTY

205. *Mineral Creek Spring*. This is known as an iron spring and is located about 4 miles up South Mineral Creek. The surroundings of the spring suggest the possibility of developing a considerable flow, but the water is very weakly mineralized. The most important constituent is ferrous bicarbonate. The water issues from a sandstone.

#### SOUTH FORK, RIO GRANDE COUNTY

206. *Million's Springs*. The group of cold springs is located on the South Fork of the Rio Grande about 5 miles above South Fork station and post office. Three of the springs have a flow of 8 to 10 gallons each per minute. They issue from a granite cut by porphyry dikes. The waters are weakly mineralized.

#### SPRINGDALE, BOULDER COUNTY

207-210. The springs are on Lefthand Creek about 8 miles northwest of Boulder, and 2 miles below the mining camp of Jamestown. They are reached by a good automobile road from Boulder.

The country rock is pre-Cambrian granite and gneiss. There are four springs yielding waters very similar in character and probably rising from the same deep source. The differences

in composition are in the proportion of the salts contained. Two are notably higher in iron bicarbonate than the others.

The total flow is sufficient to justify development, and at one time Springdale was a popular health resort. Much water was bottled and shipped. The hotel was burnt and has not been rebuilt. Some water is still used.

These waters are the most highly radioactive in the State.

#### STEAMBOAT SPRINGS, ROUTT COUNTY

211-224. This is the greatest group of springs in Colorado, and is located along the Bear or Yampa River in Routt County on the western slope of the Park Range. One of the springs which formerly made a noise resembling the puffing of a steamboat gave the name to the whole group and to the thriving town which has grown up about the springs. The Denver and Salt Lake Railway furnishes easy access to this inviting resort.

The waters of the springs vary in temperature from 56° to 104° F. The mineral content is equally variable, and the flow of the springs ranges from 1 to 2 gallons per minute to possibly 100 gallons per minute for the Bath House Spring. As a whole, the waters may be classed as *saline sulphureted*. In the flow of hydrogen sulphide gas, the springs range from a mere trace to a considerable volume. The quantity of carbon dioxide issuing is also remarkably varied from spring to spring.

The flow of several of the springs is immediately increased by rain storms, showing that the surface waters must have ready access to the spring channels. This fact makes it difficult to estimate the salinity of the spring waters proper, or the volume of water compared with the volume of water under normal conditions.

The springs are near the contact of the pre-Cambrian area of the Park Range and the steeply upturned Mesozoic sedimentary rocks flanking the mountains. The lowest and oldest of the stratified rocks are probably of Jura-Triassic age. Following these are Dakota sandstones and shales, which are, in turn, overlaid by the Mancos group. In the spring zone these sedimentary rocks are charged with sulphur and salts deposited from spring waters. At a distance from the spring area the formations have their normal appearance and composition.

In all the spring waters analyzed sodium is by far the most important base. It appears to occur mainly in the form of bicarbonate and the chloride. Next in importance as bases come potassium and calcium, but they fall far short of the rank of sodium.
